Traceroute

Decipher a Packet Route

The traceroute (or tracert on Windows) command is a useful tool to observe the route of packets towards a network host. You will learn the underlying functionality of traceroute in a later lecture. Below, you find a traceroute output from ETHZ towards the New York University (www.nyu.edu).

Look at the route the packet takes. Can you identify different ASes? At which point does it leave ETHZ?

Compare hop 9 and 10. Can you explain the huge time difference?

Execute the same traceroute command from your personal computer. Do you observe the same route? What did change?

Assuming you could execute the reverse traceroute command from the New York University towards www.tik.ethz.ch, would you expect the same route just in reverse order?
Communication over the Internet can be decomposed into independent layers. In the lecture, we have discussed the Internet protocol stack which contains 5 layers. Another often used model is the OSI (Open Systems Interconnection) model with 7 layers. Find the best matching layer for the following operations/devices. You can use the already known 5-layer model.

**a)** Bit-to-bit transmission over a link.

**b)** Encryption of a message.

**c)** A switch in a network.

**d)** Routing path search.

**e)** Adding a sequence number to each packet.

**f)** A router in a network.

**g)** A middlebox in a network performing deep packet inspection (DPI) to find malware in Web traffic.

The network on the left consists of multiple autonomous systems (AS). Single-headed arrows point from providers to their customers. Double-headed arrows represent peer connections.

**a)** For each AS, identify if it is a Tier-1, Tier-2 or Tier-3 ISP network or an IXP.

**b)** AS7 has two different providers (AS1 and AS2). How is this type of interconnection called? What are the advantages of multiple different providers for AS7? Can you see any disadvantages?
Internet Communication

The figure on the left shows a (simplified version of a) packet that was recorded at your machine’s network interface using Wireshark².

_a) What kind of activity does this packet belong to?_

_b) From the lecture, you know that a packet is composed of data in different layers. The fields in the left-hand figure are already grouped to four blocks representing the link, network, transport and application layer. Do you know which protocol is used in each of the four layers?  _Hint: You may want to have a look at the list of protocols on Wikipedia³._

c) After being sent out at your machine’s network interface, the packet will traverse a switch which will forward it based on the destination address. On which layer does the switch operate and which is the destination address it will look at?

d) After leaving your local network, the packet will traverse a router. On which layer does the router operate and which is the destination address it will look at?

Bandwidth and Delay

Network Characterization

Calculate and compare the bandwidth and the delay for different communication methods.

a) Pigeon post: Pigeons can be used as messengers. They are trained to transport messages of up to 75 g from one location to another. Assuming you want to send a USB flash drive with 16 GB\(^a\) from Zürich to a friend in Paris (500 km). Calculate the bandwidth and the delay for a pigeon travelling at an average speed of 80 km/h.

b) Pneumatic tube: These systems were introduced in the late 19th century to transport small, urgent items within buildings or even within cities. The capsules travel at an average speed of 8 m/s per second. Assuming you send an external hard drive with 2 TB\(^b\) of storage through a tube from ETZ to the main building (distance 400 m), calculate the bandwidth and delay.

c) AWS Snowmobile: Amazon uses a truck to move data from its customers to their data center. The truck houses a container which can store 100 PB\(^c\) of data.\(^d\) Assuming the truck is transporting data from New York to an AWS data center in San Francisco (distance 4700 km) at an average speed of 100 km/h per hour, calculate the bandwidth and the delay.

\(^{a}\)1 GB = 10\(^9\) bytes

\(^{b}\)1 TB = 10\(^12\) bytes

\(^{c}\)1 PB = 10\(^15\) bytes

Types of Delay

When accessing a website your data has to travel from your computer through different networks to the server on which the website resides and back.

a) You want to access the website of the University of Sydney (www.sydney.edu.au). How long does it take for a data packet to travel to the server and back (straight-line distance Zürich-Sydney 16′600 km) assuming your data packet travels at the speed of light \(3 \times 10^8\) m/s?

b) Measure the time it actually takes for a packet to travel to the server and back by issuing a ping www.sydney.edu.au in a terminal. If you don’t have a computer available you can use our measurement:

PING sydney.edu.au (129.78.5.8):

time=328.942 ms

The calculated and measured times are not even close. Why do we observe such a difference?

https://linux.die.net/man/8/ping

Application Requirements

Different applications pose different requirements to the network that need to be fulfilled for a good user experience. For each of the following applications, list their requirements in terms of bandwidth and delay (low, medium, high, not important) and explain your choices.

a) Skype audio call

b) Skype HD video call

c) Youtube video

d) Data download from cloud storage
