Communication Networks

TCP Congestion Control

Congestion control aims at solving three problems

#1	bandwidth estimation	How to adjust the bandwidth of a single flow to the bottleneck bandwidth? could be 1 Mbps or 1 Gbps…
#2	bandwidth adaptation	How to adjust the bandwidth of a single flow to variation of the bottleneck bandwidth?
#3	fairness	How to share bandwidth “fairly" among flows, without overloading the network

Congestion control differs from flow control

both are provided by TCP though

Flow control	prevents one fast sender from overloading a slow receiver
Congestion control	prevents a set of senders from overloading the network

The sender adapts its sending rate
based on these two windows

Receiving Window RWND	How many bytes can be sent without overflowing the receiver buffer? based on the receiver input
Congestion Window CWND	How many bytes can be sent without overflowing the routers? based on network conditions
Sender Window	minimum(CWND, RWND)

The 2 key mechanisms of Congestion Control

detecting congestion

reacting to congestion

The 2 key mechanisms of Congestion Control

detecting congestion

reacting to congestion

Detecting losses can be done using ACKs or timeouts, the two signal differ in their degree of severity

duplicated ACKs

mild congestion signal

packets are still making it

timeout

severe congestion signal

multiple consequent losses

The 2 key mechanisms of Congestion Control

detecting congestion

reacting to congestion

TCP approach is to gently increase when not congested and to rapidly decrease when congested

question

What increase/decrease function should we use?

it depends on the problem we are solving…

Congestion control aims at solving three problems

#1	bandwidth estimation	How to adjust the bandwidth of a single flow to the bottleneck bandwidth? could be 1 Mbps or 1 Gbps…
#2	bandwidth adaptation	How to adjust the bandwidth of a single flow to variation of the bottleneck bandwidth?
#3	fairness	How to share bandwidth “fairly" among flows, without overloading the network

#1 bandwidth estimation

How to adjust the bandwidth of a single flow to the bottleneck bandwidth?

could be 1 Mbps or 1 Gbps…

Initially, you want to quickly get a first-order estimate of the available bandwidth

Intuition	Start slow but rapidly increase until a packet drop occurs	
Increase policy	cwnd = 1	initially
	cwnd += 1	upon receipt of an ACK

#2 bandwidth adaptation

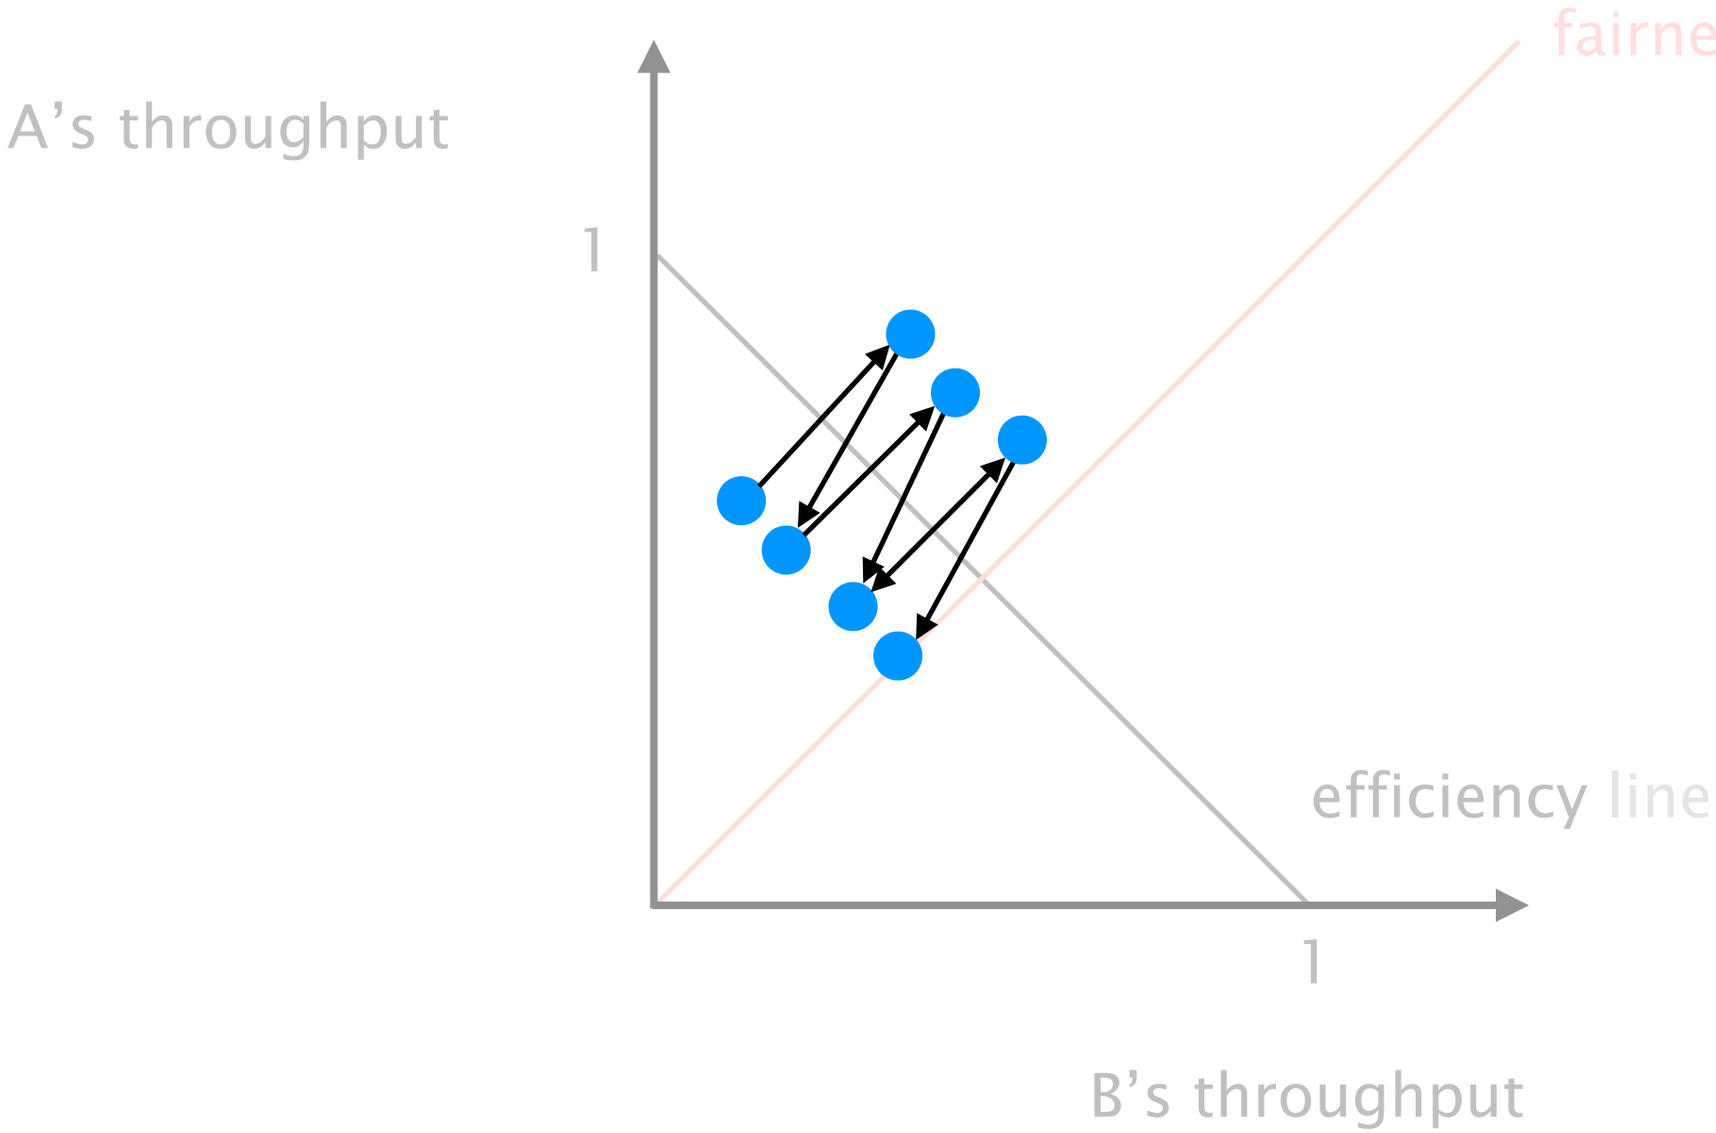
How to adjust the bandwidth of a single flow to variation of the bottleneck bandwidth?

	increase behavior	decrease behavior
AIAD	gentle	gentle
AIMD	gentle	aggressive
MIAD	aggressive	gentle
MIMD	aggressive	aggressive

#3 fairness

How to share bandwidth “fairly" among flows, without overloading the network

AIMD converge to fairness and efficiency,
it then fluctuates around the optimum (in a stable way)



TCP congestion control in less than 10 lines of code

Initially:

```
    cwnd = 1
    ssthresh = infinite
```

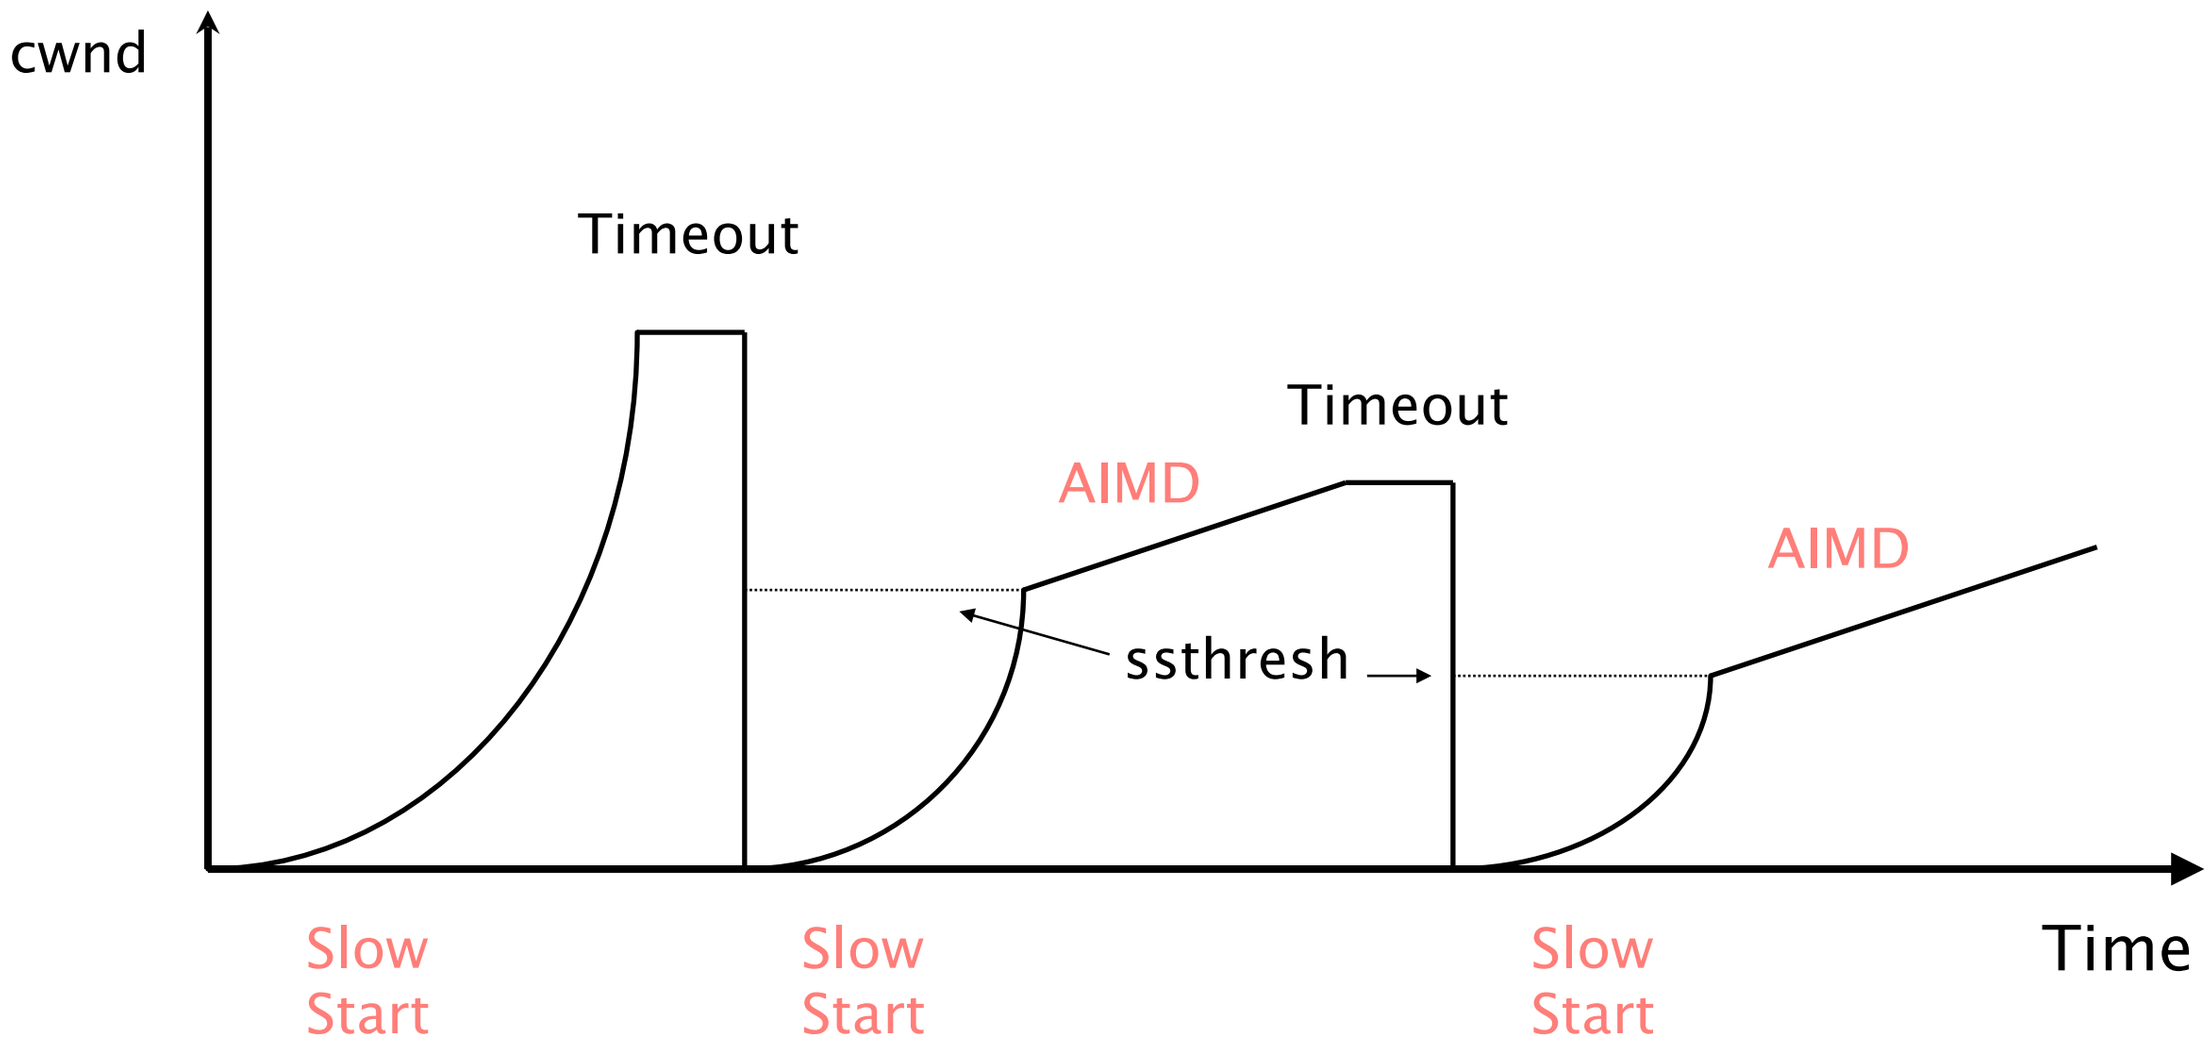
New ACK received:

```
    if (cwnd < ssthresh):
        /* Slow Start*/
        cwnd = cwnd + 1
    else:
        /* Congestion Avoidance */
        cwnd = cwnd + 1/cwnd
```

Timeout:

```
    /* Multiplicative decrease */
    ssthresh = cwnd/2
    cwnd = 1
```

The congestion window of a TCP session typically undergoes multiple cycles of slow-start/AIMD



Going back all the way back to 0 upon timeout completely destroys throughput

solution

Avoid timeout expiration…

which are usually >500ms

Detecting losses can be done using ACKs or timeouts, the two signal differ in their degree of severity

duplicated ACKs	mild congestion signal packets are still making it
timeout	severe congestion signal multiple consequent losses

TCP automatically resends a segment after receiving 3 duplicates ACKs for it

this is known as a “fast retransmit”

After a fast retransmit, TCP switches back to AIMD,

without going all way the back to 0

this is known as “fast recovery”

TCP congestion control (almost complete)

Initially:
```
    cwnd = 1
    ssthresh = infinite
```
New ACK received:
```
    if (cwnd < ssthresh):
        /* Slow Start*/
        cwnd = cwnd + 1
    else:
        /* Congestion Avoidance */
        cwnd = cwnd + 1/cwnd
    dup_ack = 0
```
Timeout:
```
    /* Multiplicative decrease */
    ssthresh = cwnd/2
    cwnd = 1
```

Duplicate ACKs received:
```
    dup_ack ++;
    if (dup_ack >= 3):
        /* Fast Recovery */
        ssthresh = cwnd/2
        cwnd = ssthresh
```

Initially:

```
    cwnd = 1
    ssthresh = infinite
```

New ACK received:

```
    if (cwnd < ssthresh):
        /* Slow Start*/
        cwnd = cwnd + 1
    else:
        /* Congestion Avoidance */
        cwnd = cwnd + 1/cwnd
    dup_ack = 0
```

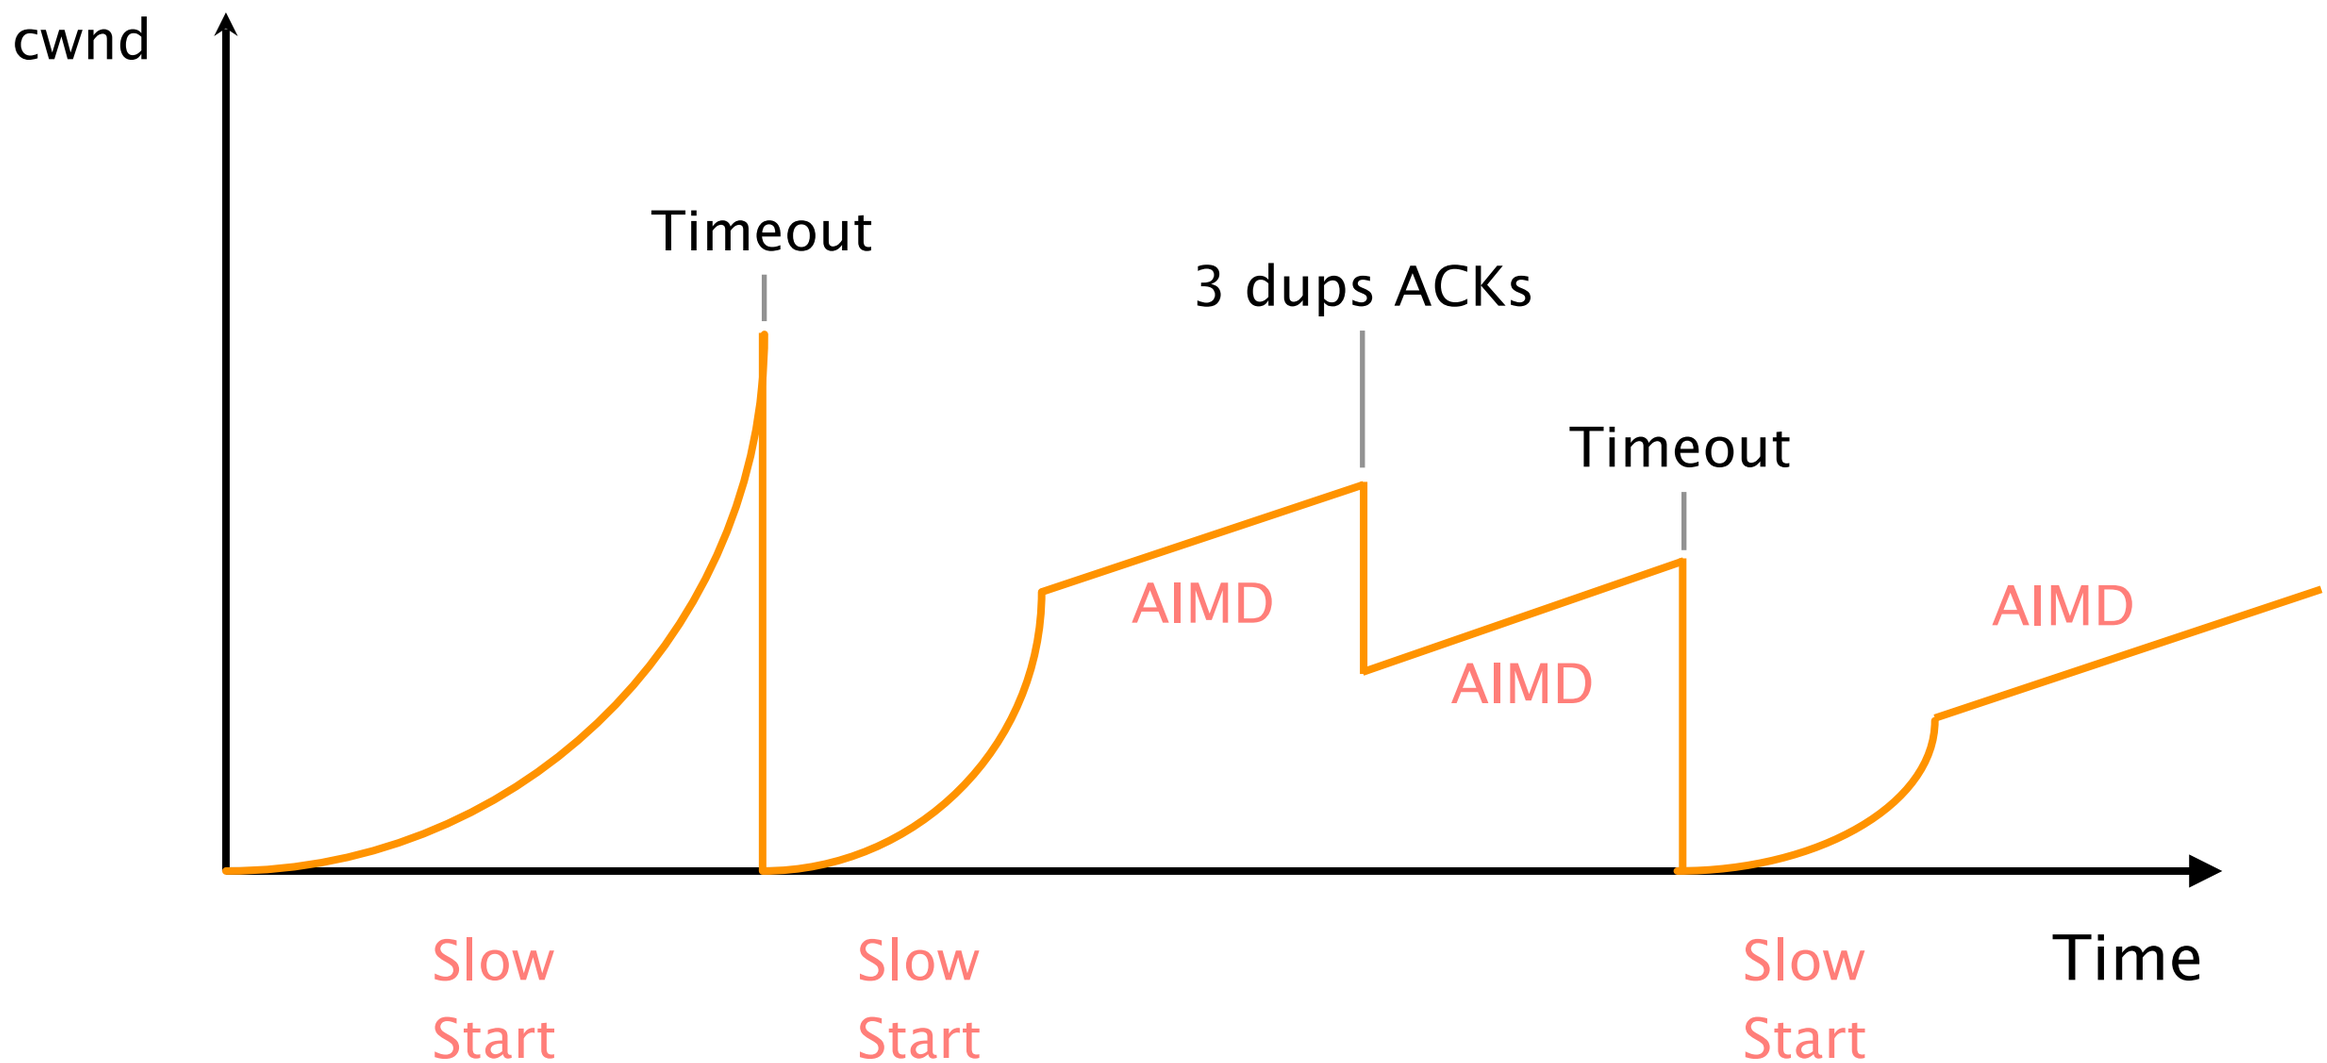
Timeout:

```
    /* Multiplicative decrease */
    ssthresh = cwnd/2
    cwnd = 1
```

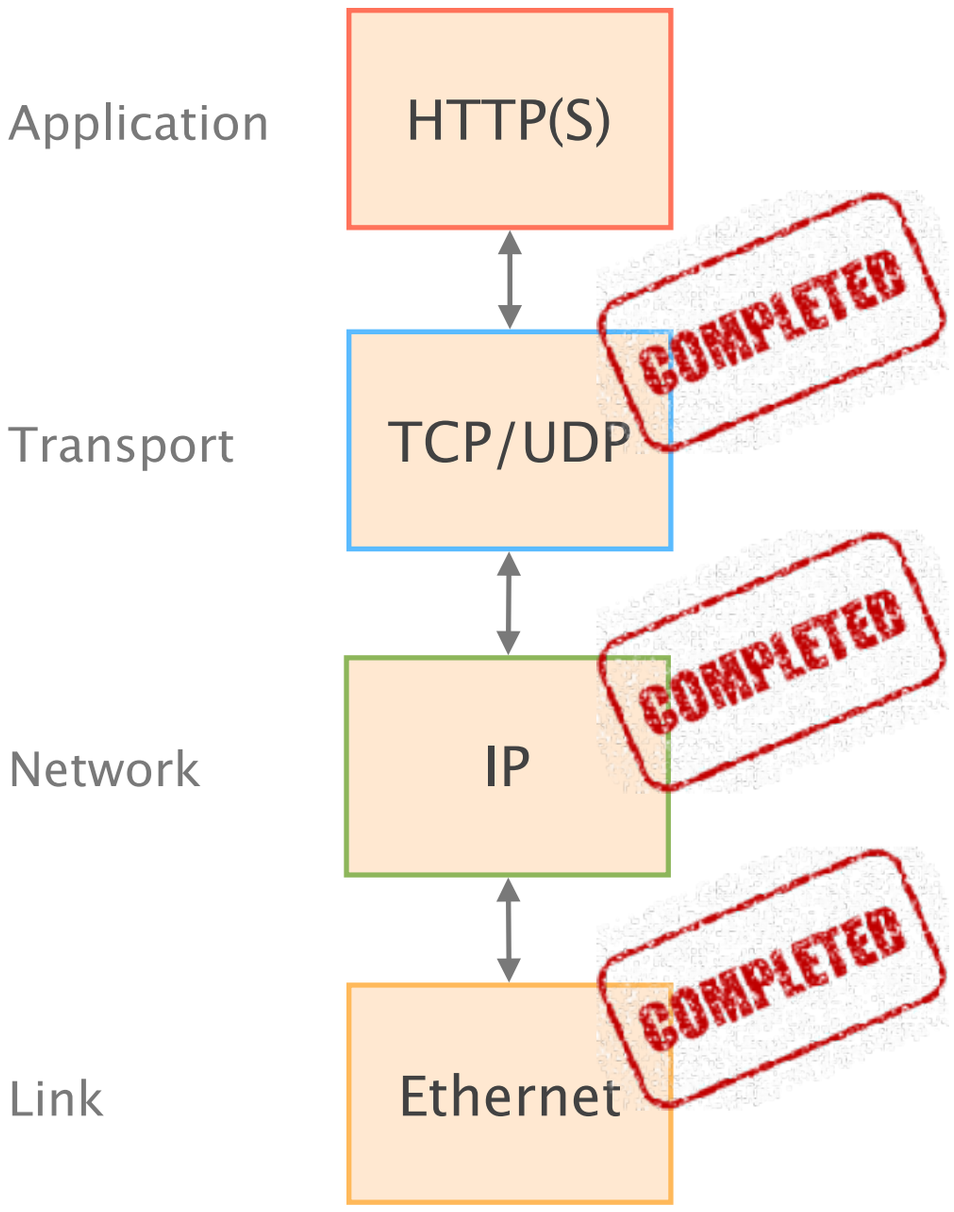
Duplicate ACKs received:

```
    dup_ack ++;
    if (dup_ack >= 3):
        /* Fast Recovery */
        ssthresh = cwnd/2
        cwnd = ssthresh
```

Congestion control makes TCP throughput look like a “sawtooth”



We now have completed the transport layer (!)



Reliable (or unreliable) transport

Best-effort global packet delivery

Best-effort local packet delivery

This week on

Communication Networks

DNS

Web

google.ch ⟷ 172.217.16.131

http://www.google.ch

DNS

Web

google.ch ⟷ 172.217.16.131

Internet has one global system for

- addressing hosts IP

  by design

- naming hosts DNS

  by "accident", an afterthought

Internet has one global system for

- naming hosts DNS

  by "accident", an afterthought

Using Internet services can be divided into four logical steps

step 1	A person has name of entity she wants to access	www.ethz.ch
step 2	She invokes an application to perform the task	Chrome
step 3	The application invokes DNS to resolve the name into an IP address	129.132.19.216
step 4	The application invokes transport protocol to establish an app-to-app connection	

The DNS system is a distributed database
which enables to resolve a name into an IP address

www.ethz.ch 129.132.19.216

In practice,
names can be mapped to more than one IP

name	DNS	IP address	
www.ethz.ch	⟷	129.132.19.216	
www.google.ch	⟷	195.176.255.241	(load-balancing)
		195.176.255.245	

In practice,

IPs can be mapped by more than one name

www.ethz.ch	129.132.19.216
www.vanbever.eu	188.165.240.60
www.routeur.be	188.165.240.60

How does one resolve a name into an IP?

initially

all host to address mappings were in a file called hosts.txt

in /etc/hosts

problem

scalability in terms of query load & speed management

consistency

availability

When you need… more flexibility,

you add… a layer of indirection

When you need… more scalability,

you add… a hierarchical structure

To scale,

DNS adopt three intertwined hierarchies

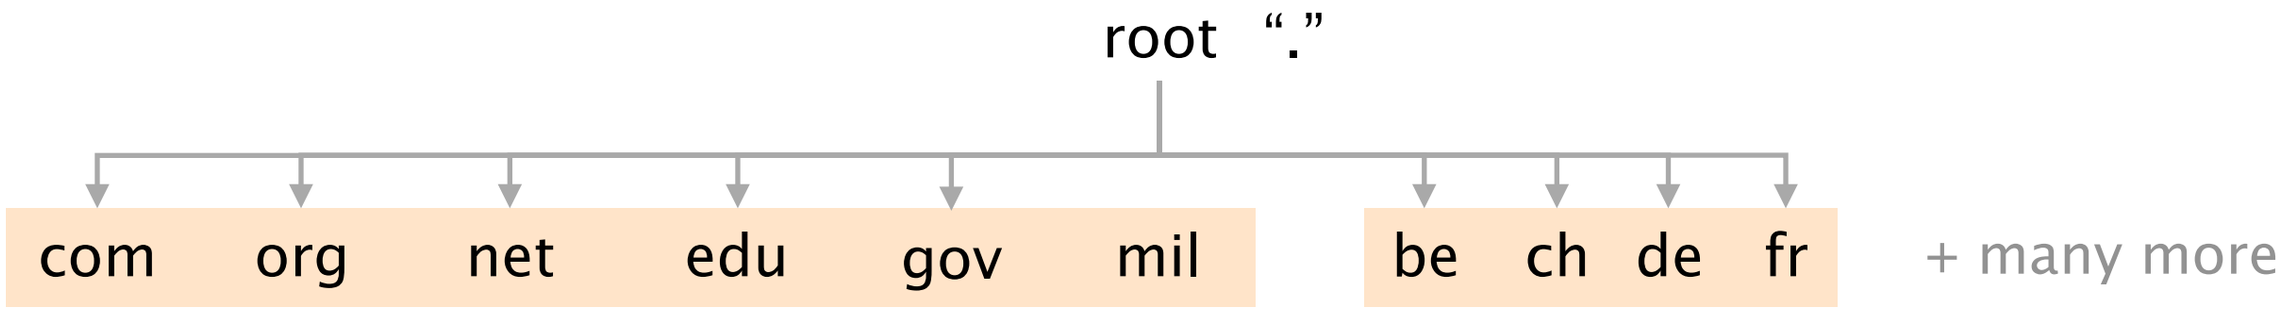
naming structure	hierarchy of addresses https://www.ee.ethz.ch/de/departement/
management	hierarchy of authority over names
infrastructure	hierarchy of DNS servers

naming structure

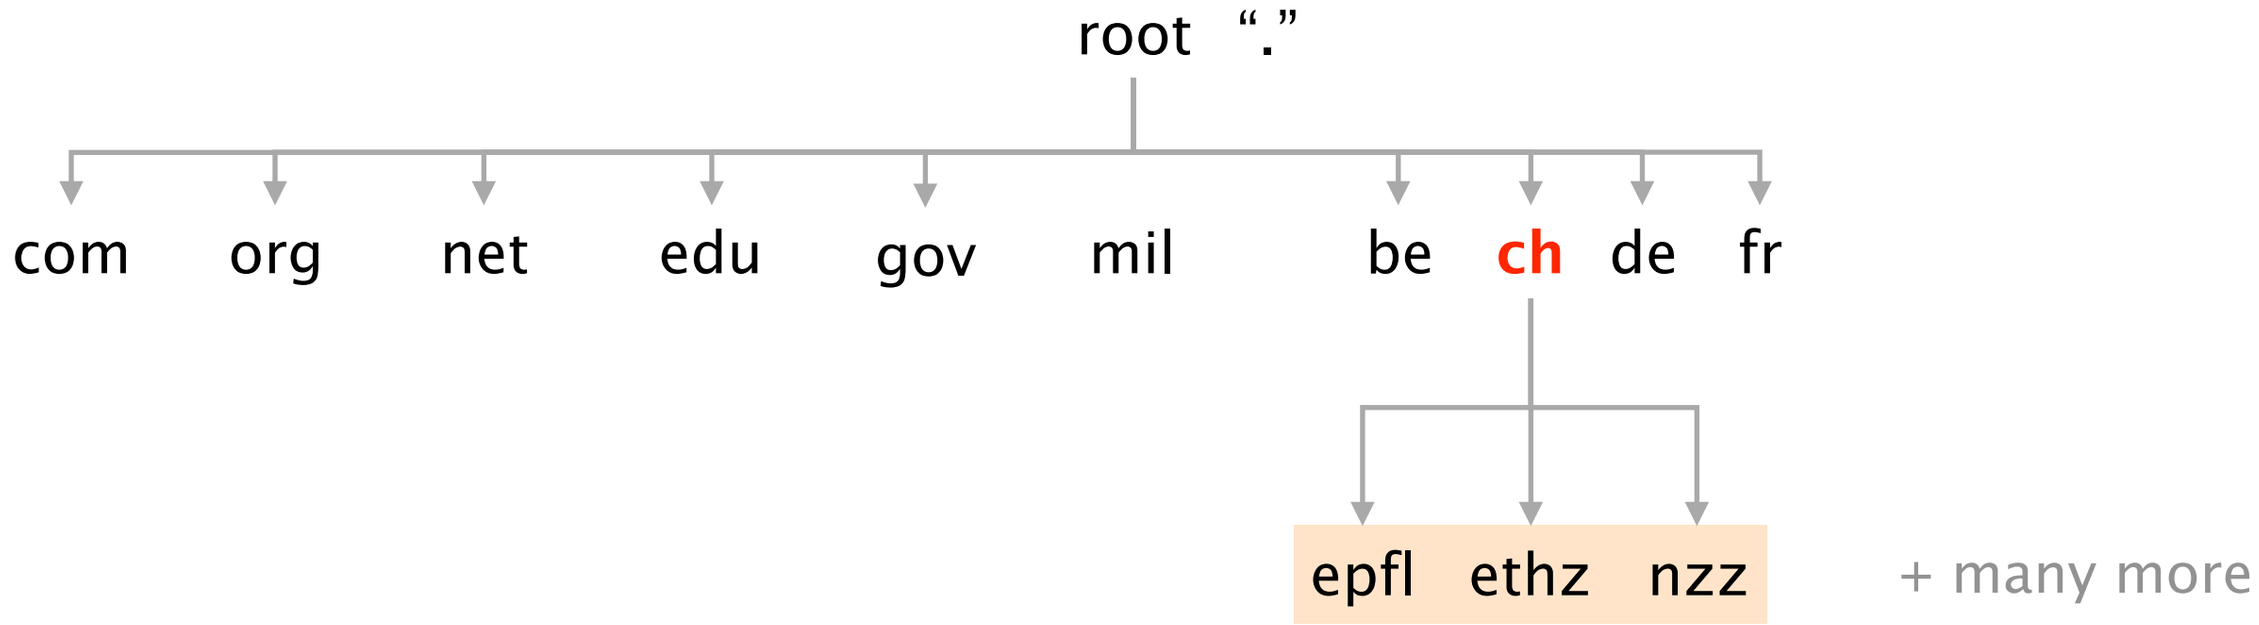
addresses are hierarchical

https://www.ee.ethz.ch/de/departement/

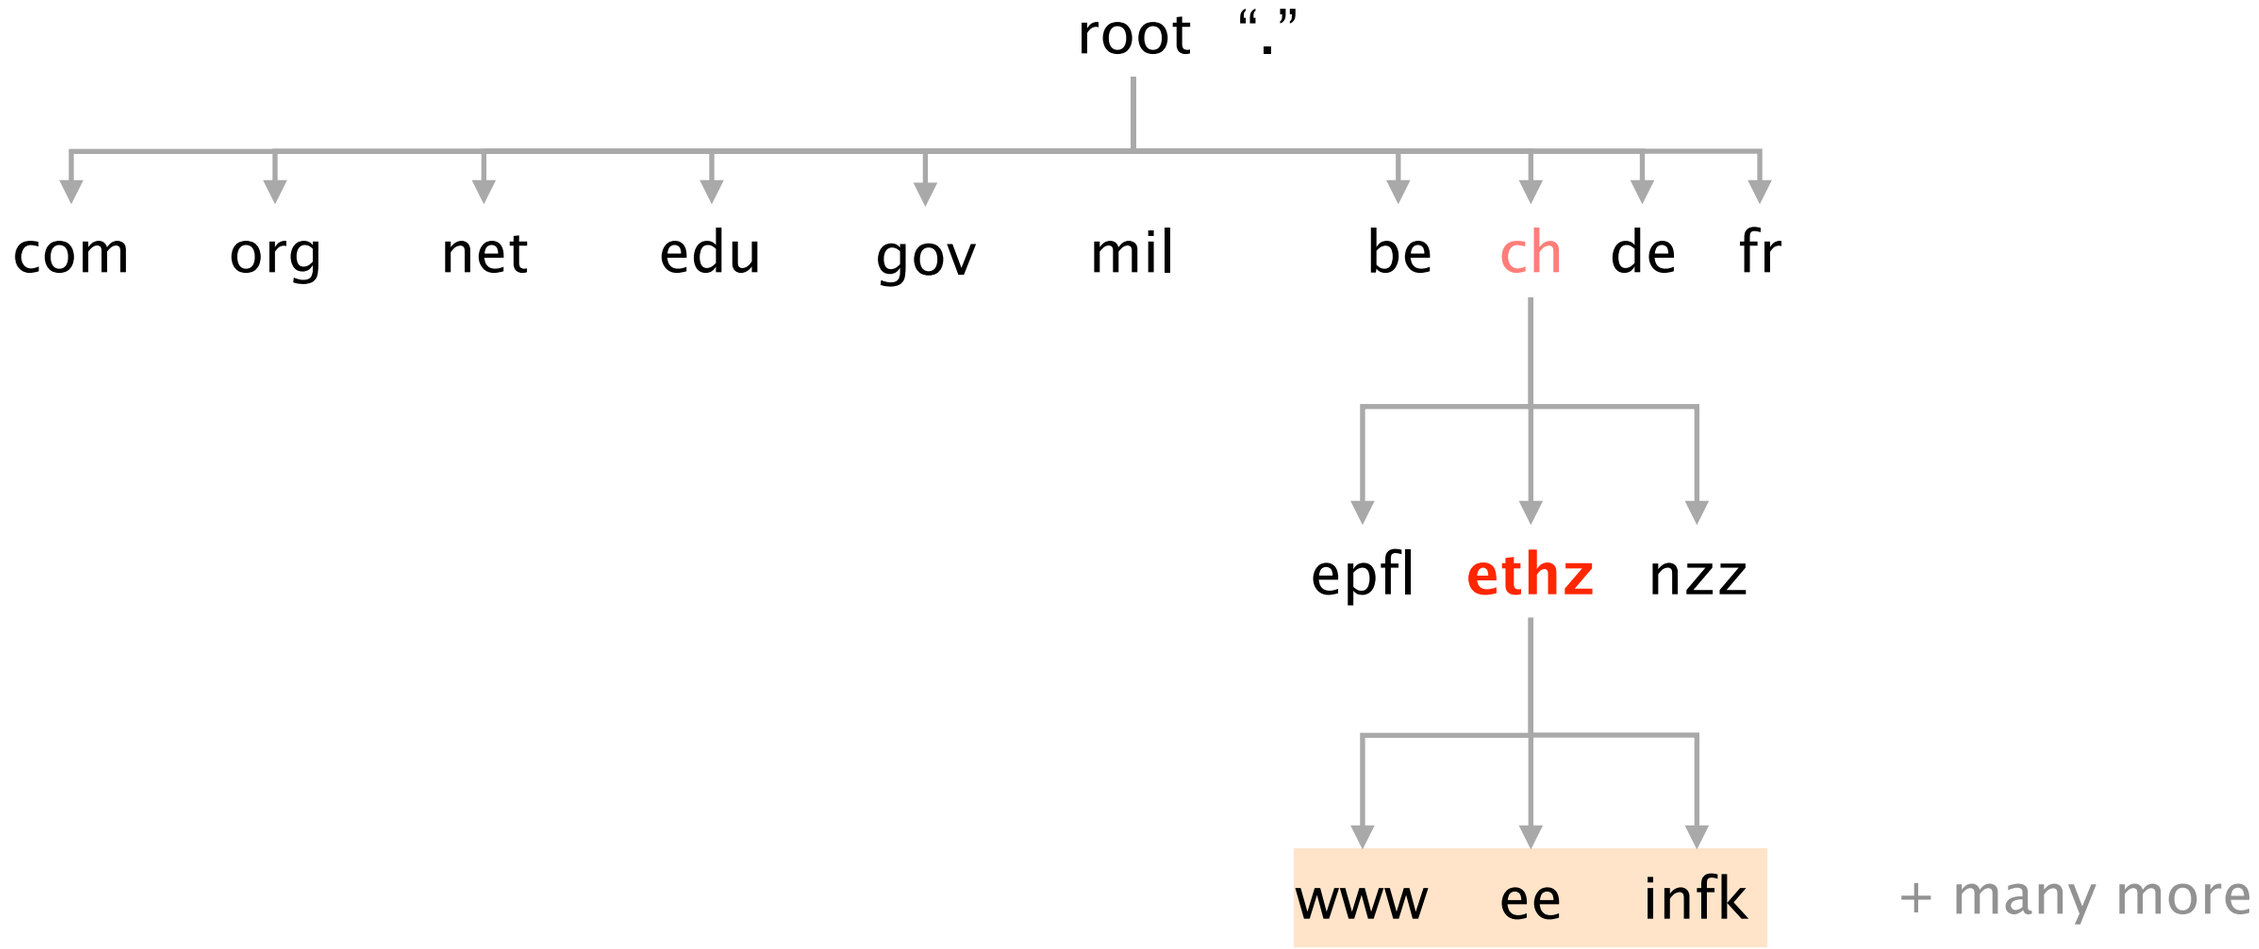
Top Level Domain (TLDs) sit at the top



Domains are subtrees



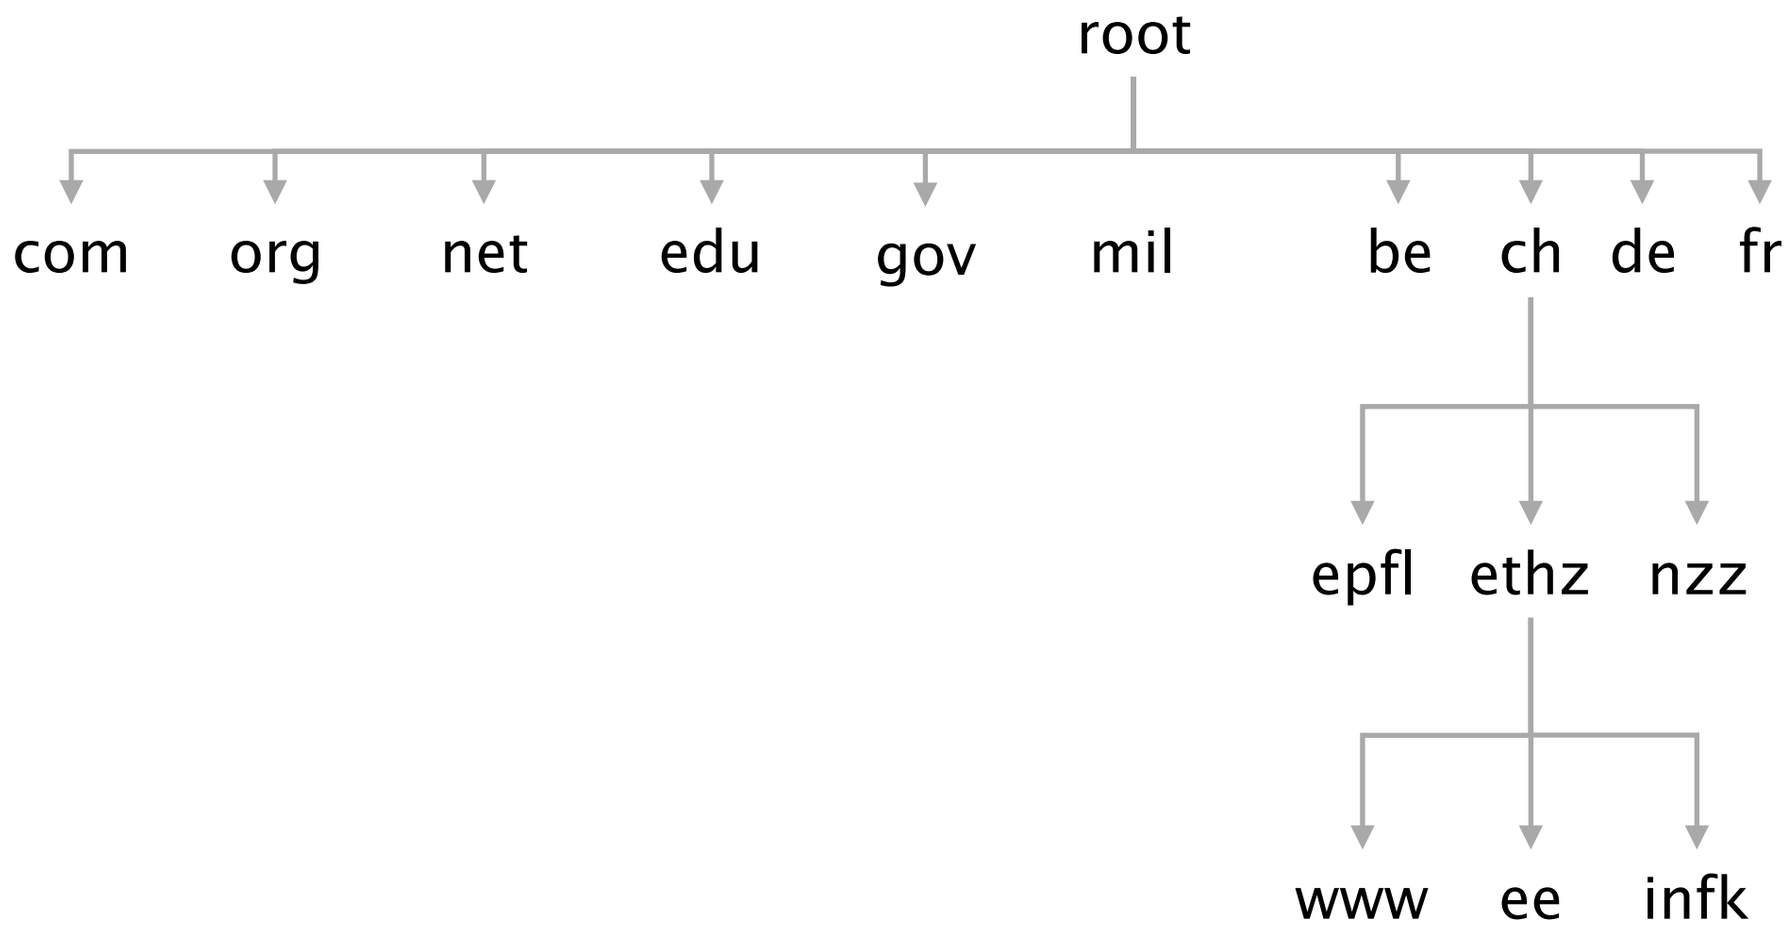
A name, *e.g.* ee.ethz.ch, represents
a leaf-to-root path in the hierarchy

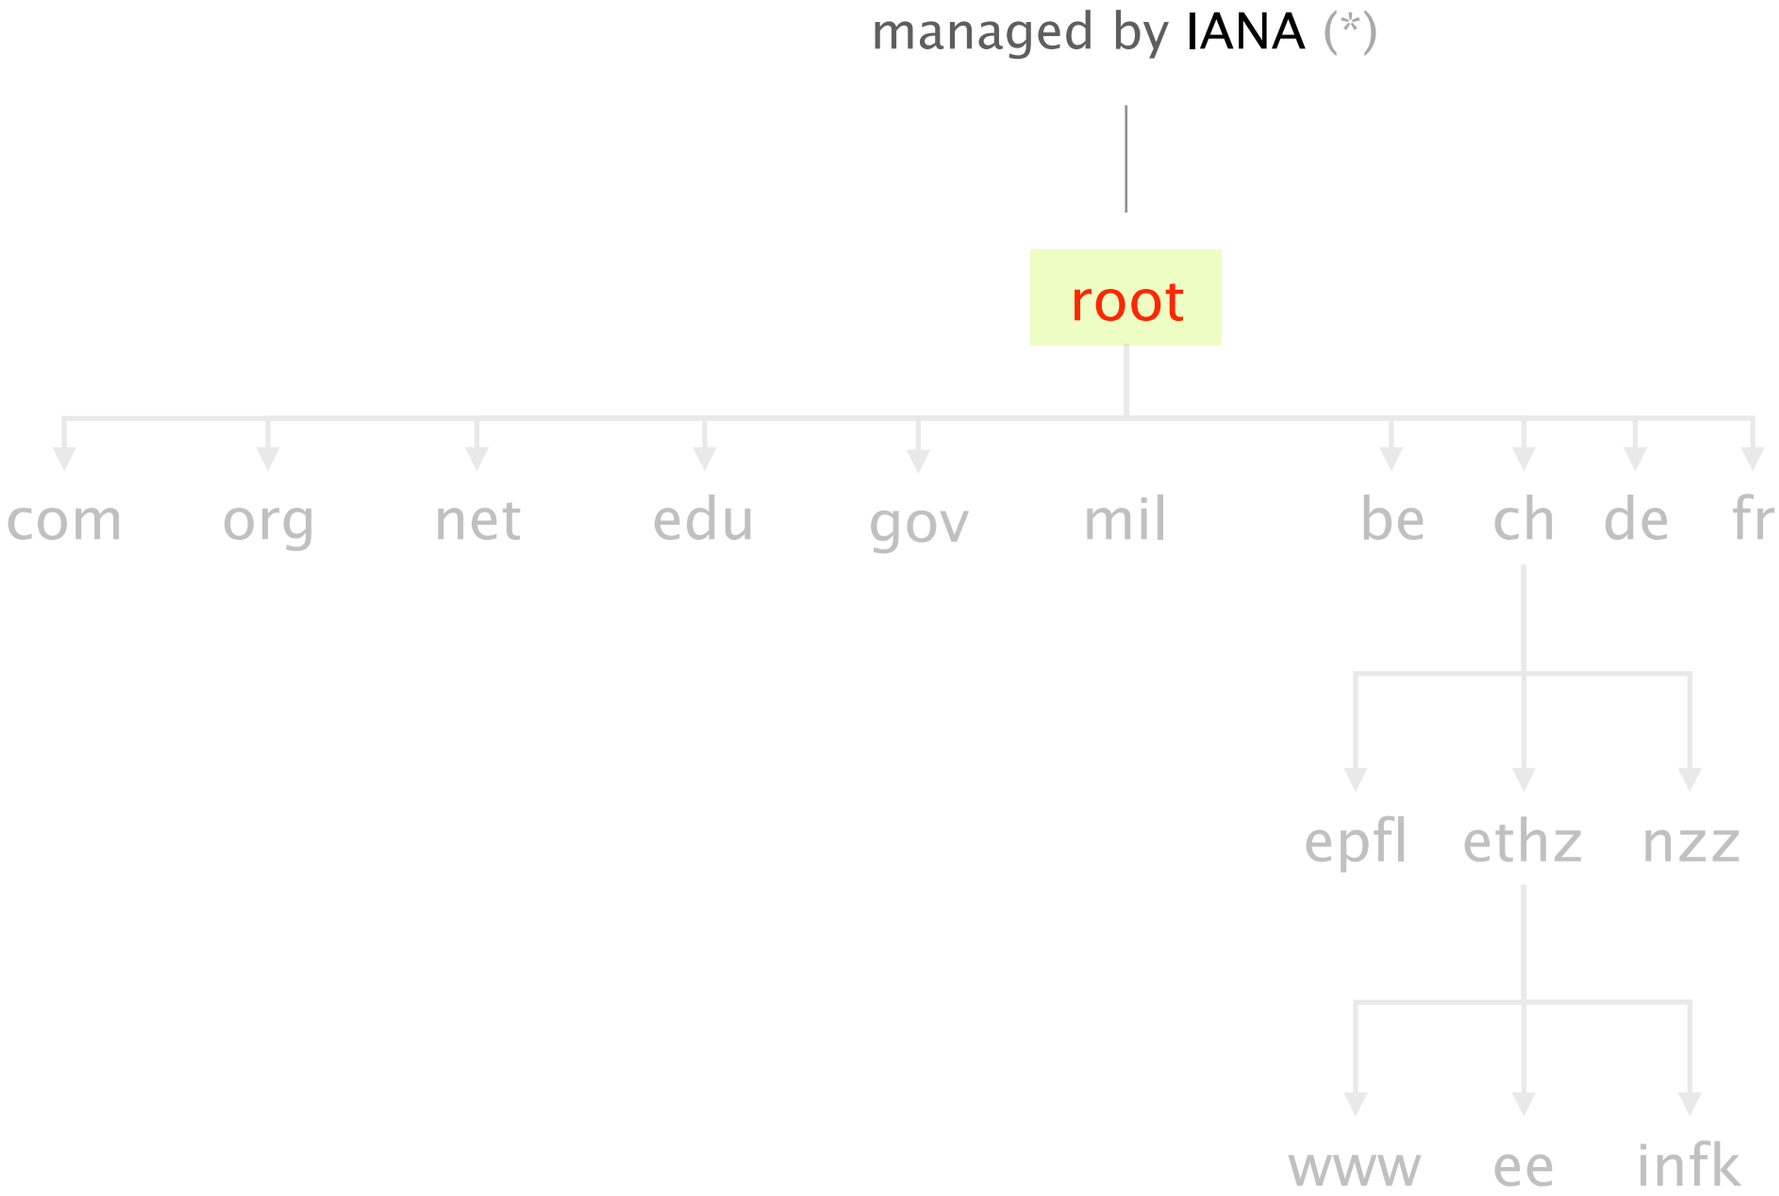


management

hierarchy of authority
over names

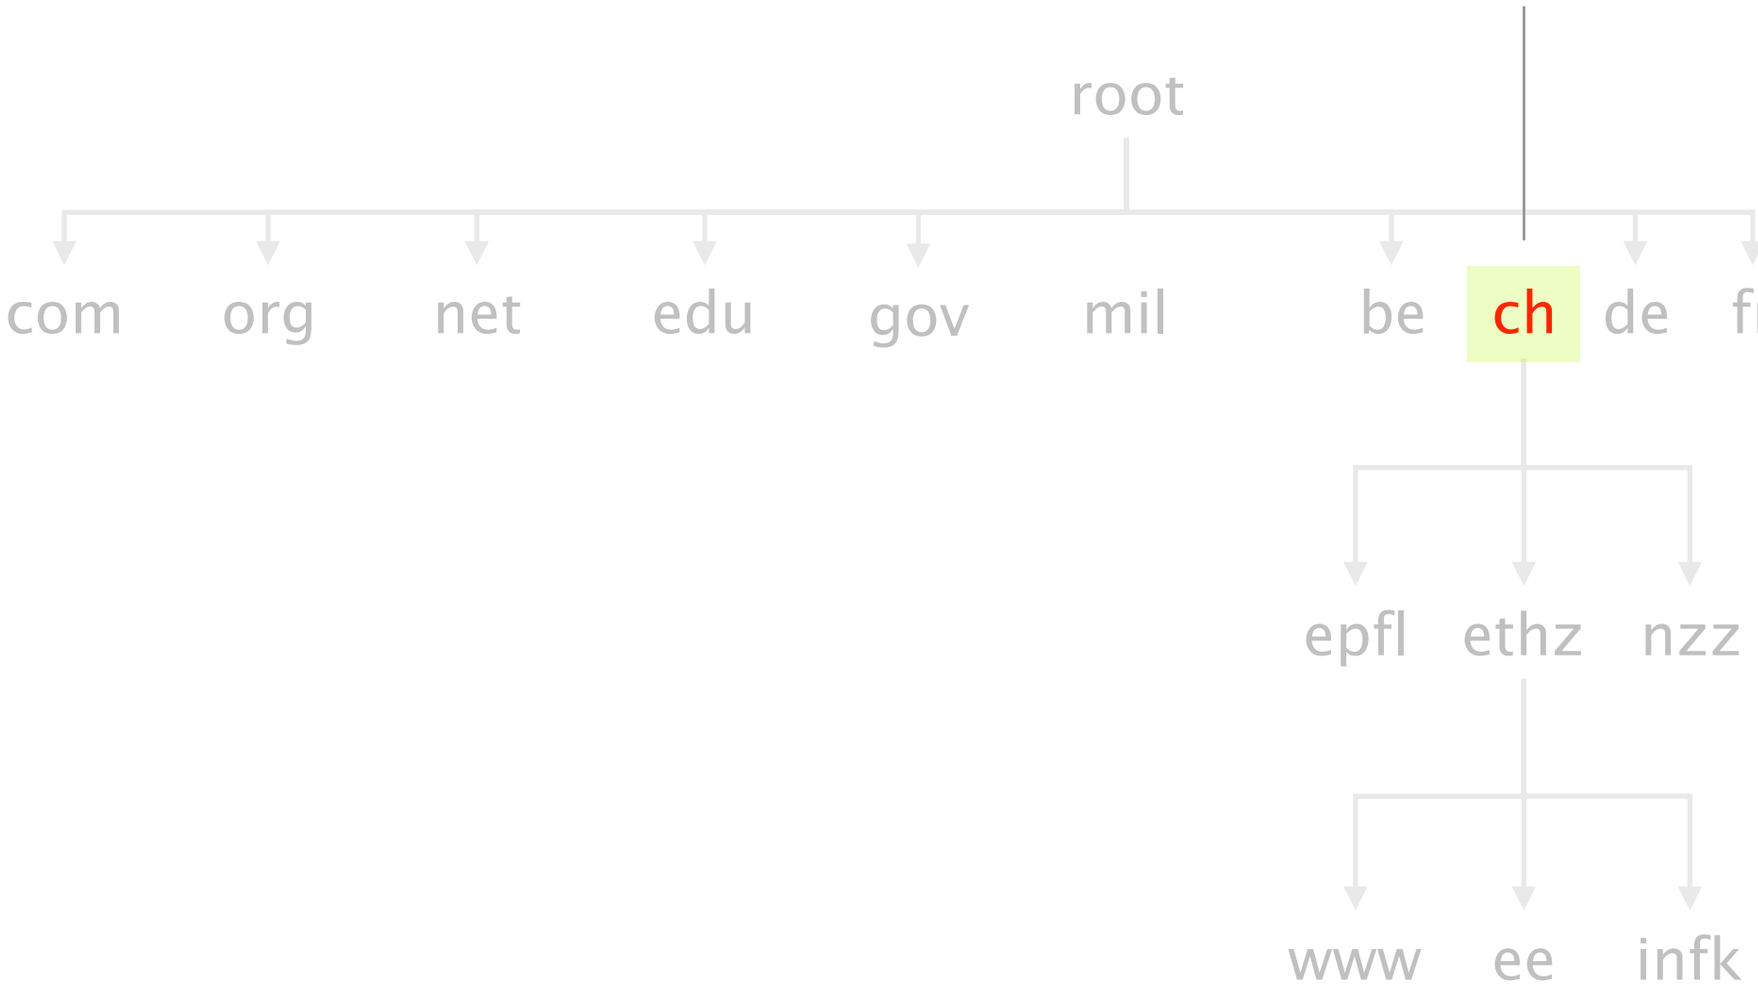
The DNS system is hierarchically administered





(*) see http://www.iana.org/domains/root/db

managed by The Swiss Education & Research Network (*)



(*) see https://www.switch.ch/about/id/

managed by

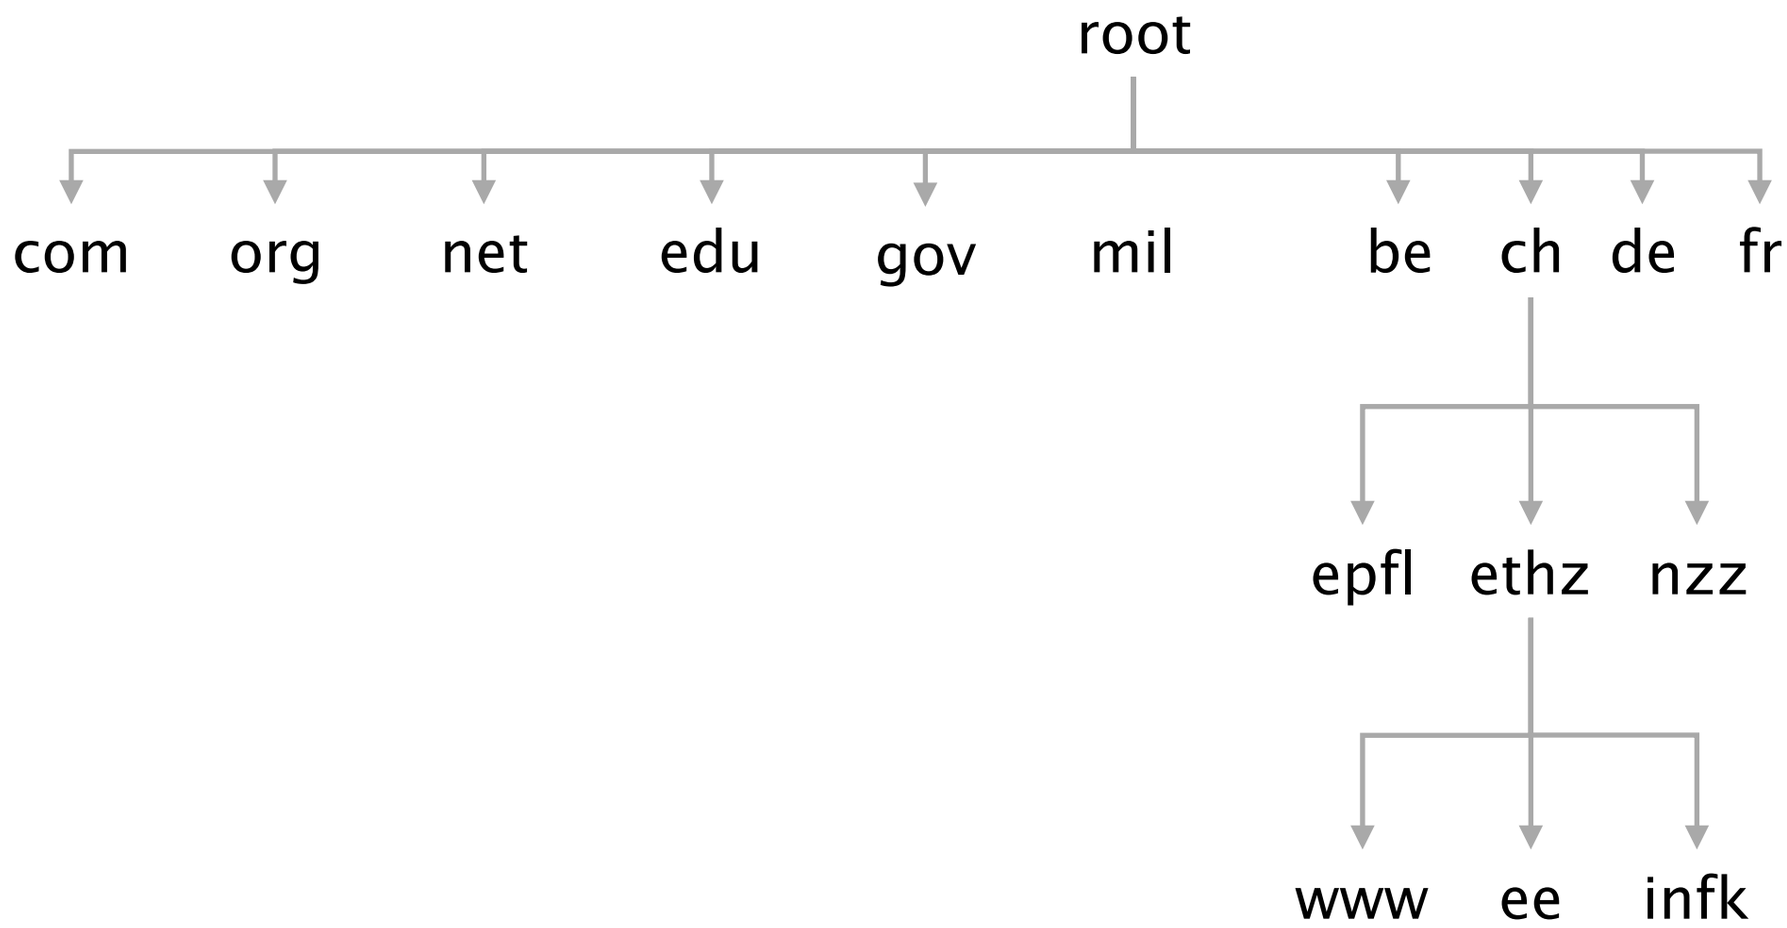
ETH Zürich
Informatikdienste ICT-Networks

Hierarchical administration means
that name collision is trivially avoided

infrastructure

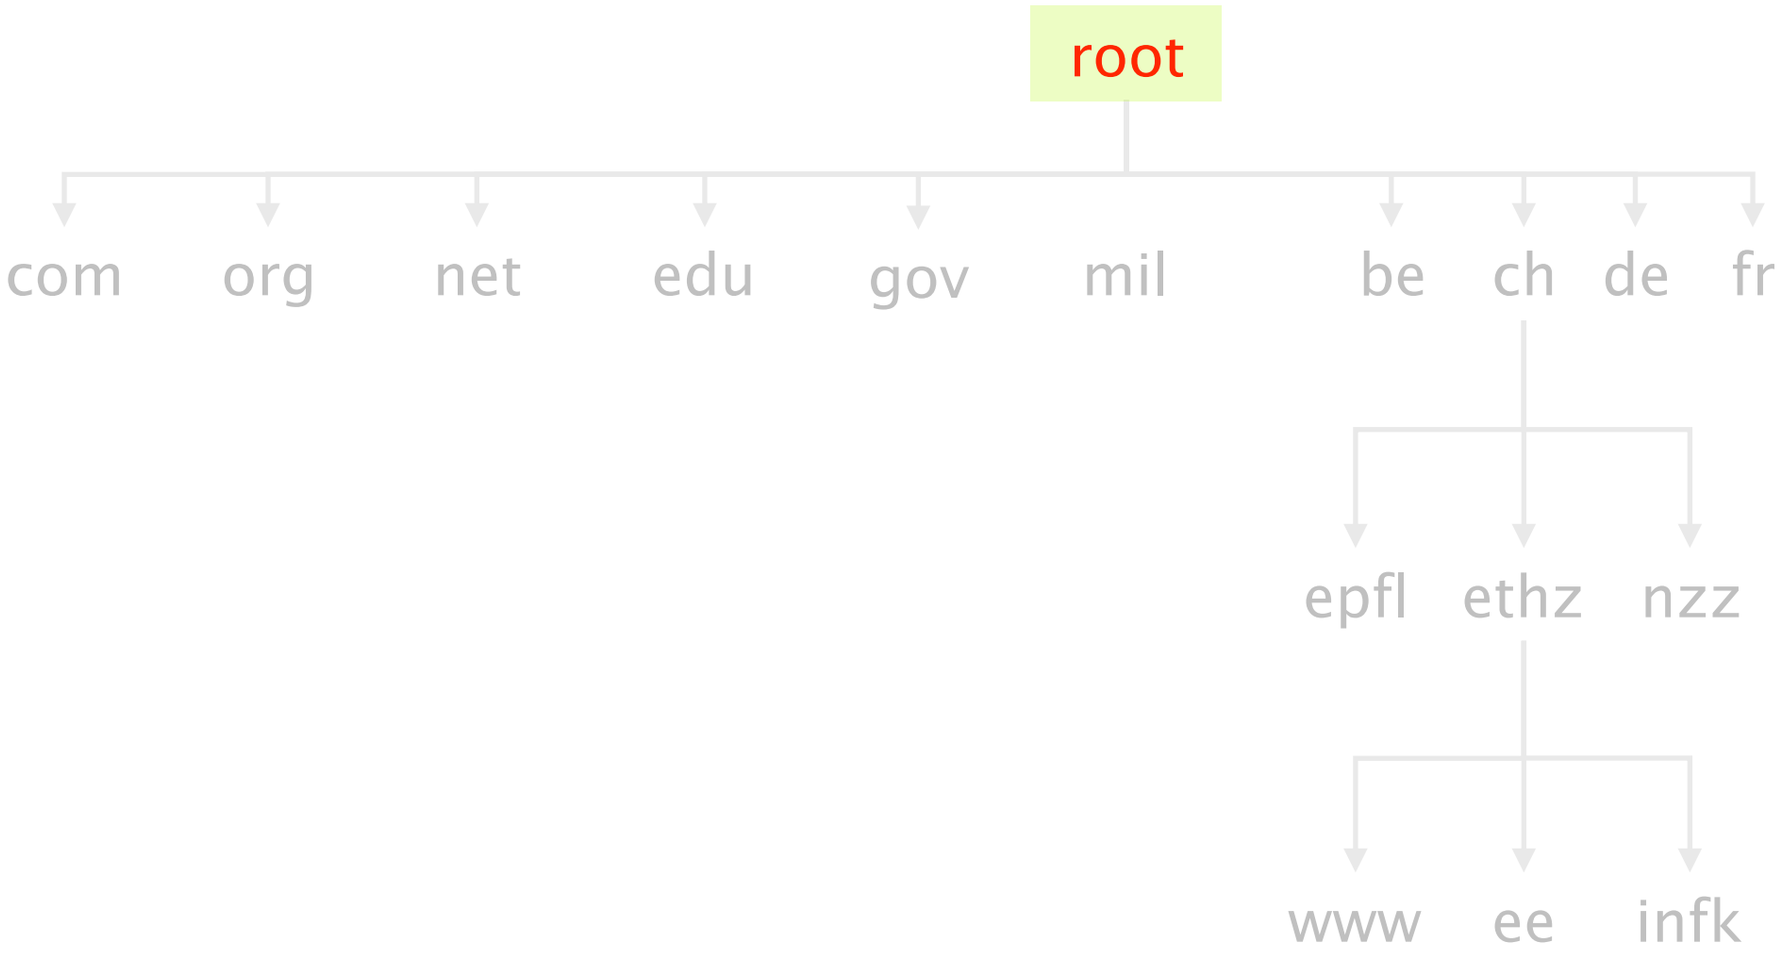
hierarchy of DNS servers

The DNS infrastructure is hierarchically organized



13 root servers (managed professionally)

serve as root (*)



(*) see http://www.root-servers.org/

RE-400
PC CARD
ROUTER.A S-IX.K.RIPE.NET
K.ROOT-SERVERS.NET
AMS-IX
SERVICE
CISCO 7301

To scale root servers,
operators rely on BGP anycast

Intuition

Routing finds shortest-paths

If several locations announce the same prefix,
then routing will deliver the packets to
the “closest” location

This enables seamless replications of resources

IP traffic
193.0.14.129
IP traffic
193.0.14.129

Do you see any problems in performing load-balancing this way?

Instances of the k-root server (*) are hosted in more than 40 locations worldwide

(*) see k.root-servers.org

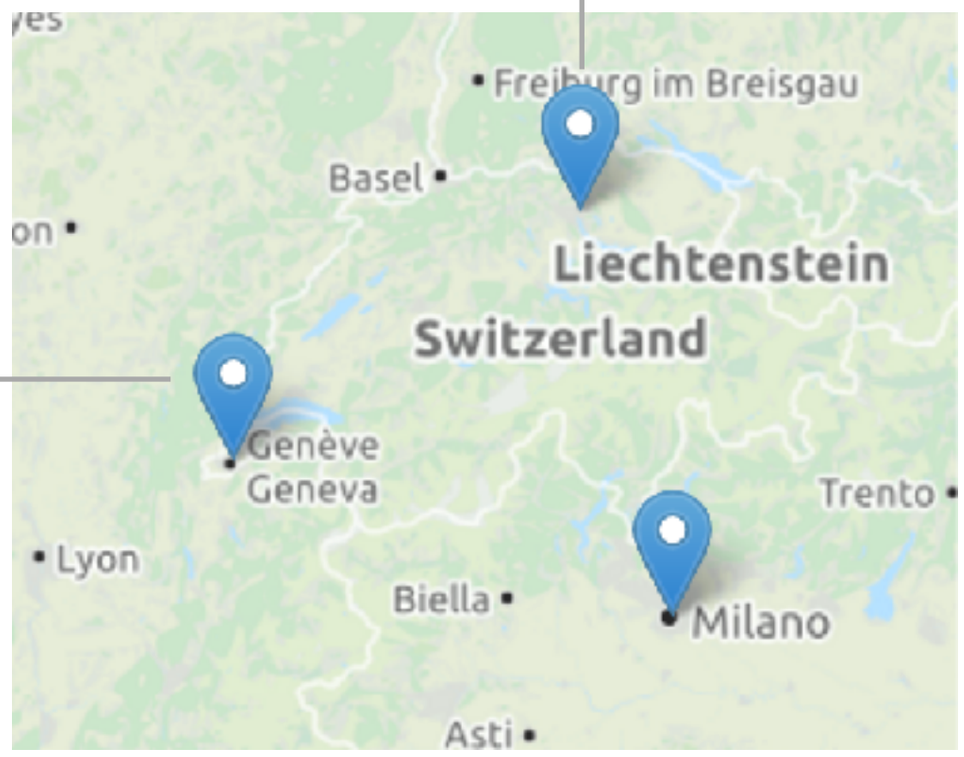
Two of these locations are in Switzerland: in Zürich and in Geneva

Swiss Internet Exchange

ns1.ch-zrh.k.ripe.net

CERN

ns1.ch-gva.k.ripe.net



All locations announce 193.0.14.0/23 in BGP,

with 193.0.14.129 being the IP of the server

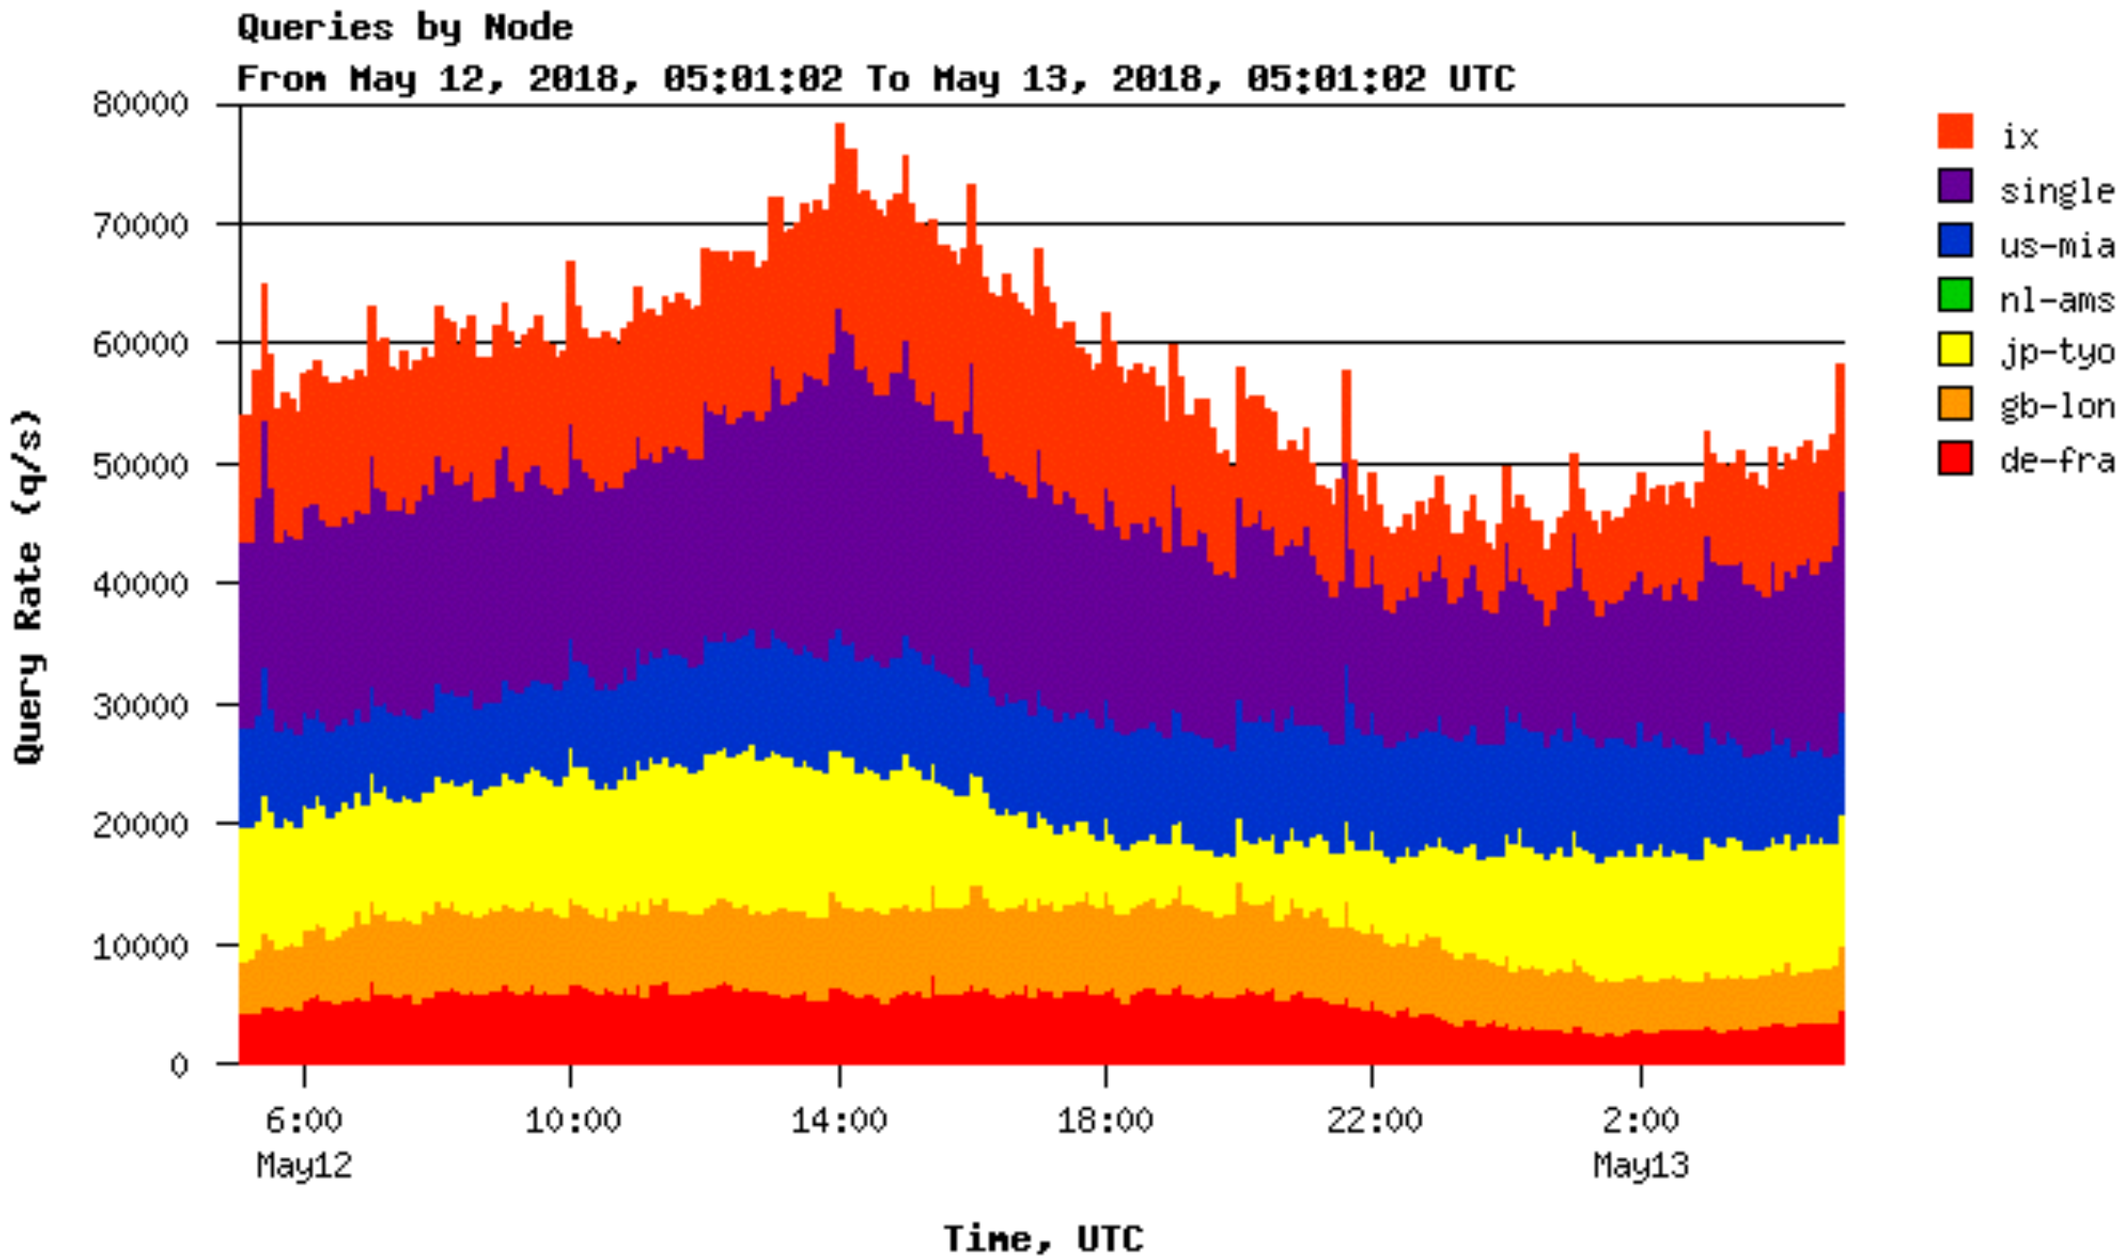
Two of these locations are in Switzerland:

in Zürich and in Geneva

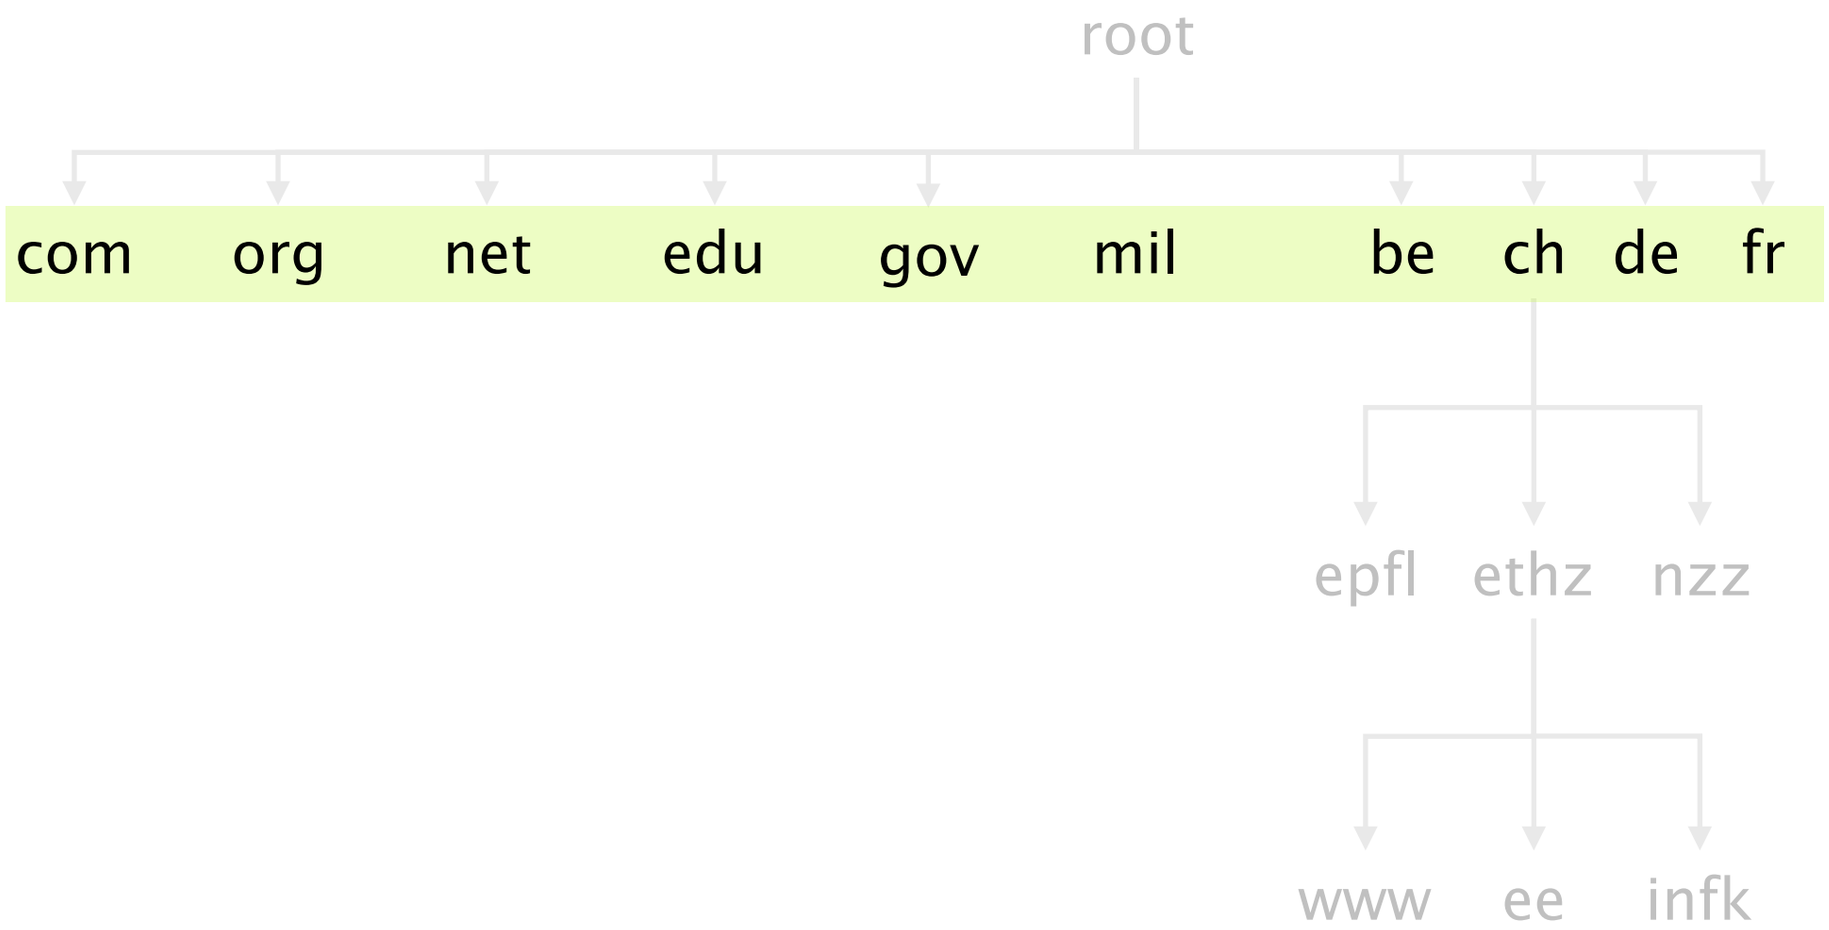
Do you mind guessing which one we use, here… in Zürich?

Each instance receives up to 70k queries per second

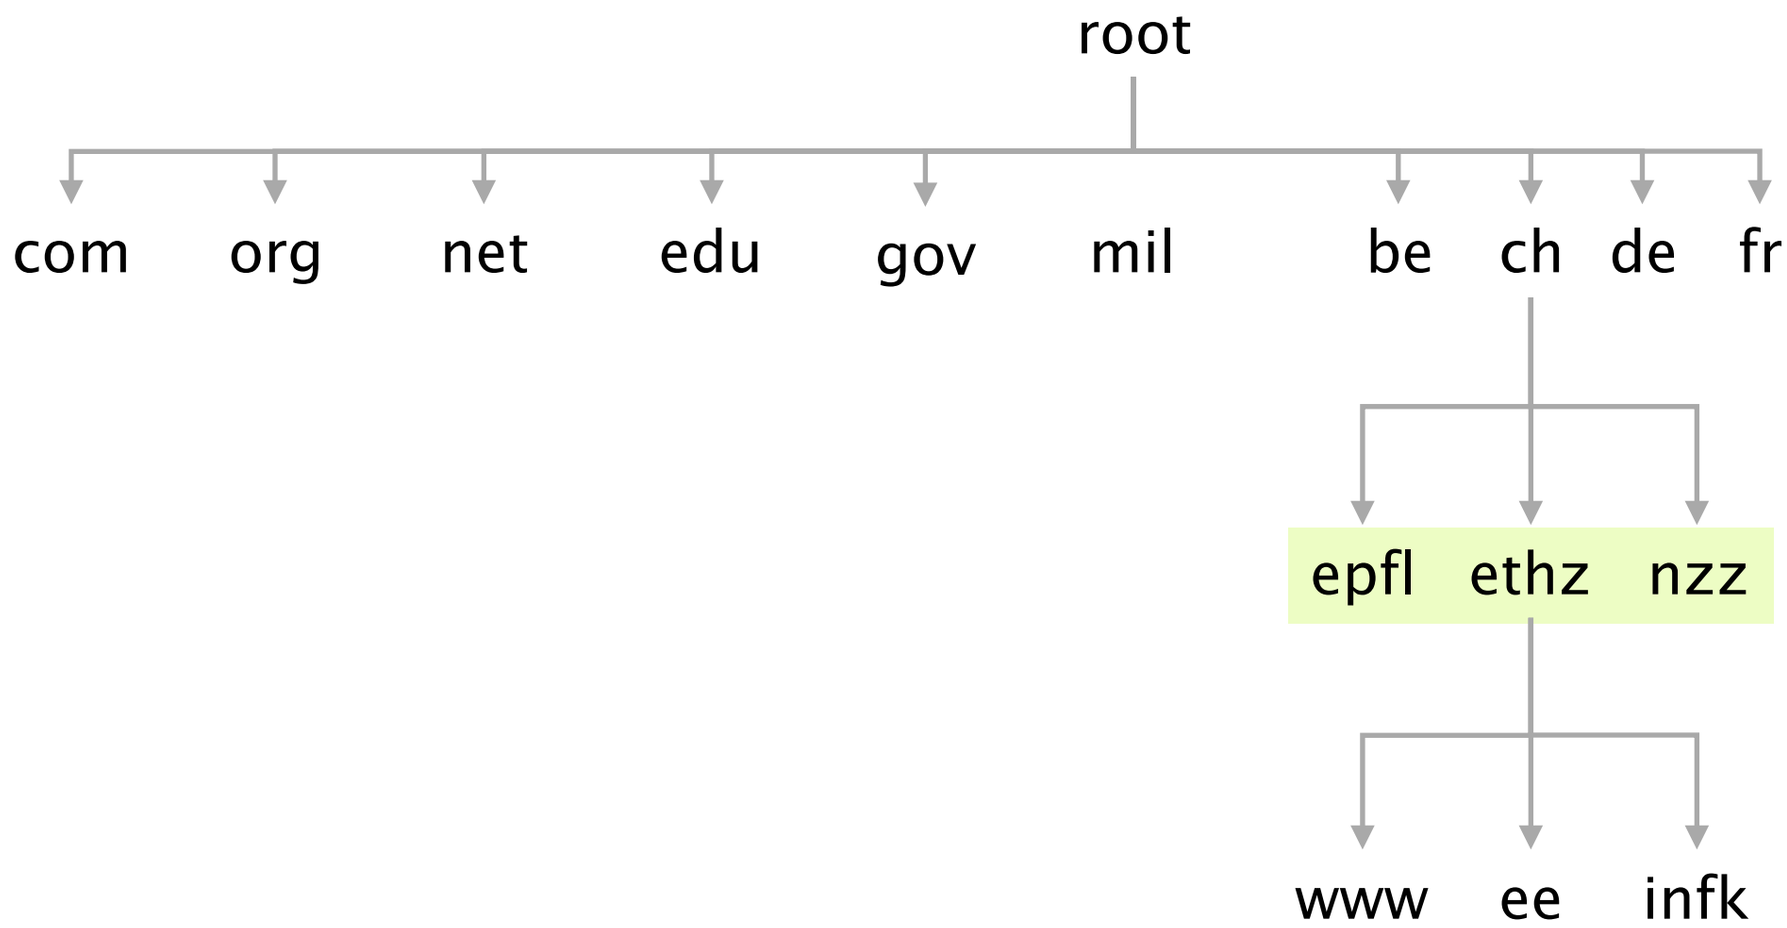
summming up to more than 4 billions queries per day



TLDs server are also managed professionally by private or non-profit organization



The bottom (and bulk) of the hierarchy is managed by Internet Service Provider or locally

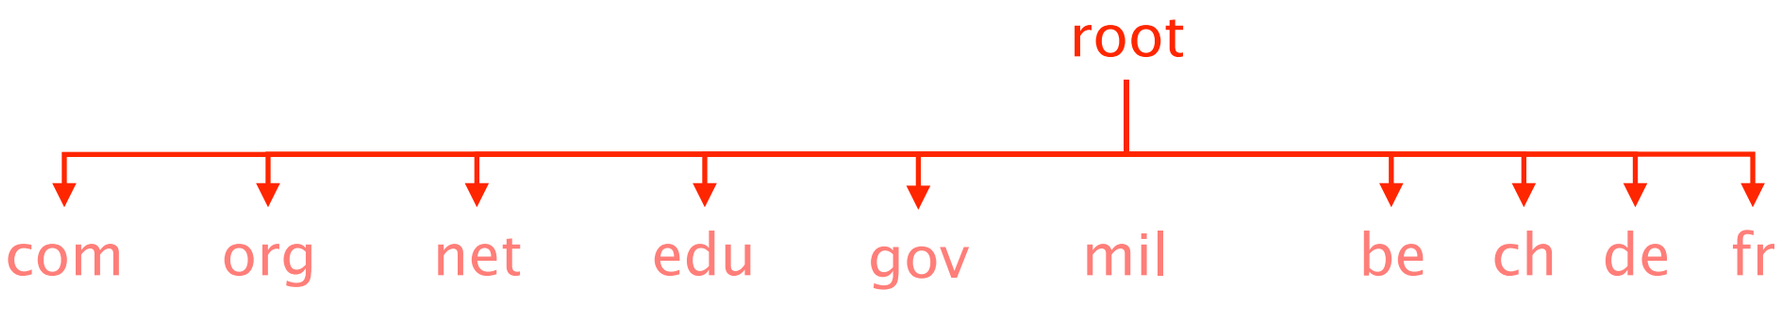


Every server knows the address of the root servers (*)

required for bootstrapping the systems

(*) see https://www.internic.net/domain/named.root

Each root server knows
the address of all TLD servers

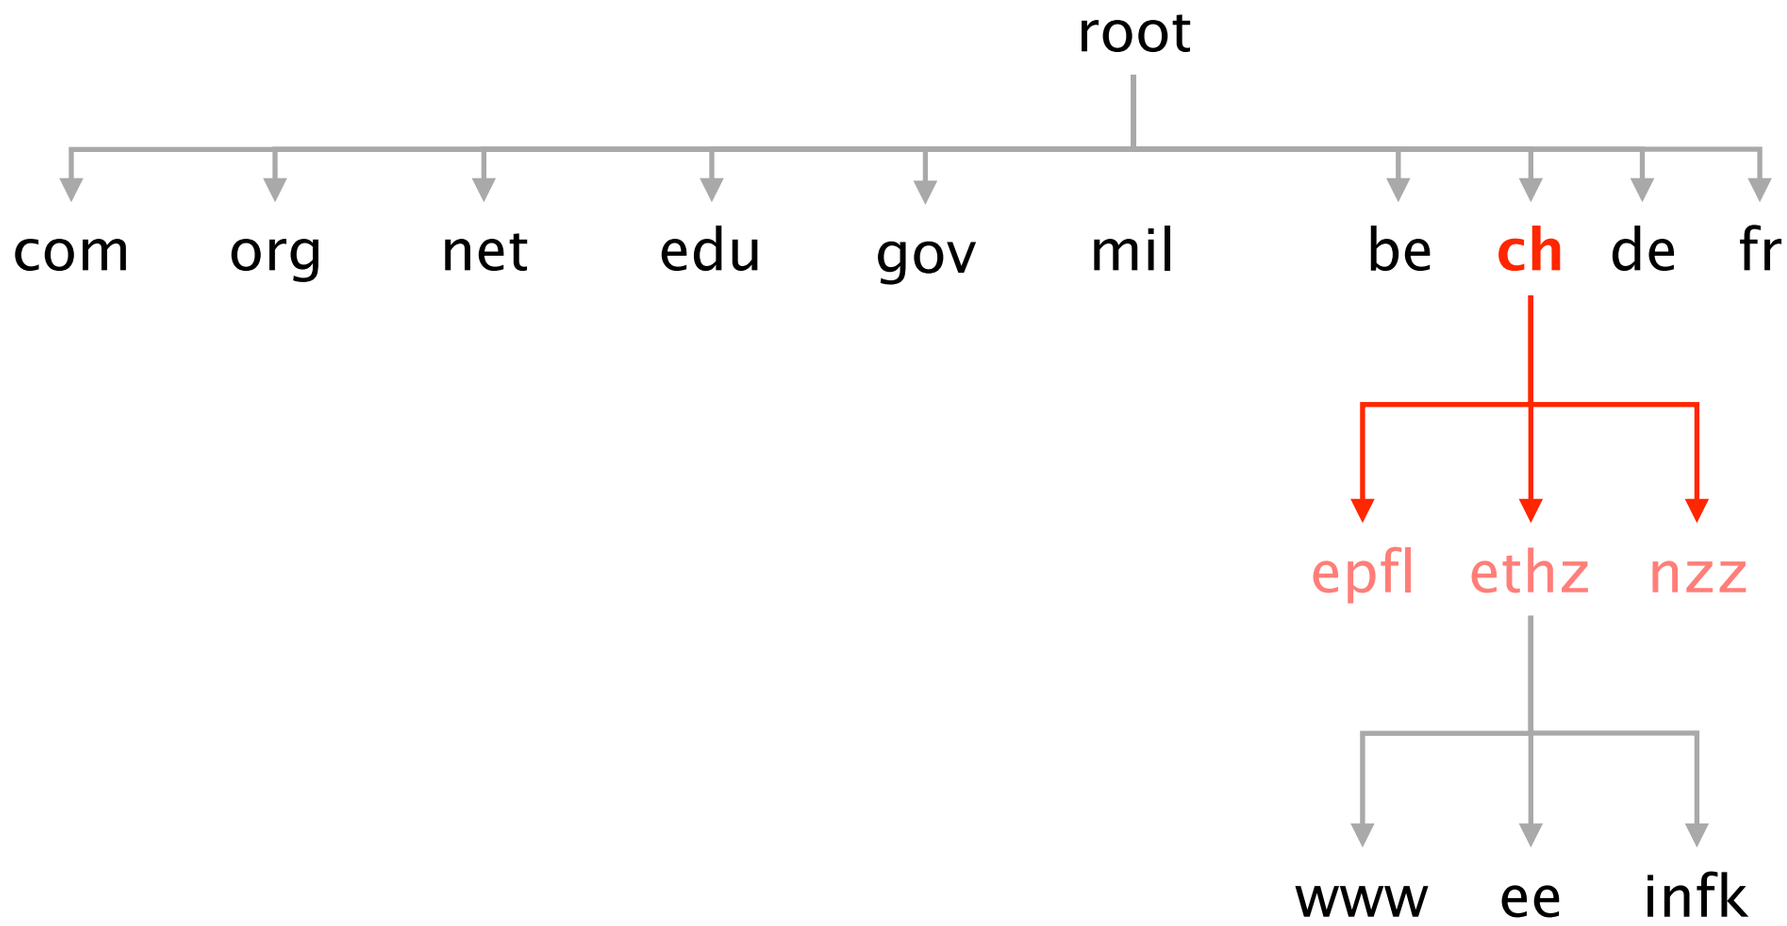


```
lvanbever:~$ dig @a.root-servers.net ch.

ch.                     172800  IN      NS      a.nic.ch.
ch.                     172800  IN      NS      b.nic.ch.
ch.                     172800  IN      NS      c.nic.ch.
ch.                     172800  IN      NS      d.nic.ch.
ch.                     172800  IN      NS      e.nic.ch.
ch.                     172800  IN      NS      f.nic.ch.
ch.                     172800  IN      NS      h.nic.ch.
```

From there on,
each server knows the address of all children

Any .ch DNS server knowns
the addresses of all sub-domains



To scale,

DNS adopt three intertwined hierarchies

naming structure	addresses are hierarchical https://www.ee.ethz.ch/de/departement/
management	hierarchy of authority over names
infrastructure	hierarchy of DNS servers

To ensure availability, each domain must have at least a primary and secondary DNS server

Ensure name service availability

as long as one of the servers is up

DNS queries can be load-balanced

across the replicas

On timeout, client use alternate servers

exponential backoff when trying the same server

Overall, the DNS system is highly scalable, available, and extensible

scalable	#names, #updates, #lookups, #users, but also in terms of administration
available	domains replicate independently of each other
extensible	any level (including the TLDs) can be modified independently

You've founded next-startup.ch and want to host it yourself, how do you insert it into the DNS?

You register next-startup.ch at a registrar *X*

e.g. Swisscom or GoDaddy

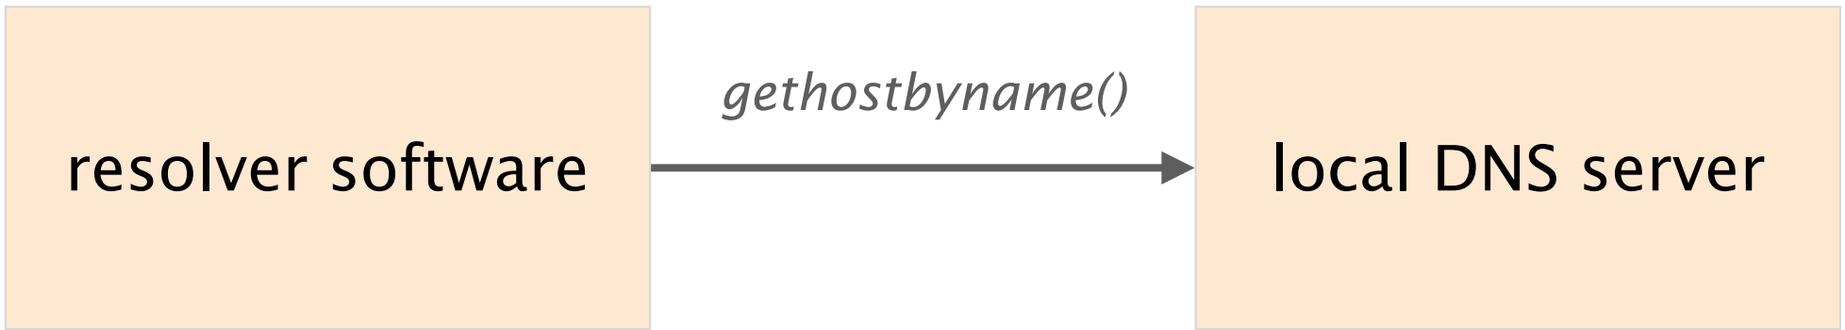
Provide *X* with the name and IP of your DNS servers

e.g., [ns1.next-startup.ch,129.132.19.253]

You set-up a DNS server @129.132.19.253

define A records for www, MX records for next-startup.ch…

Using DNS relies on two components



trigger resolution process

send request to local DNS server

usually, near the endhosts

configured statically (resolv.conf)

or dynamically (DHCP)

DNS query and reply uses UDP (port 53),
reliability is implemented by repeating requests (*)

(*) see Book (Section 5)

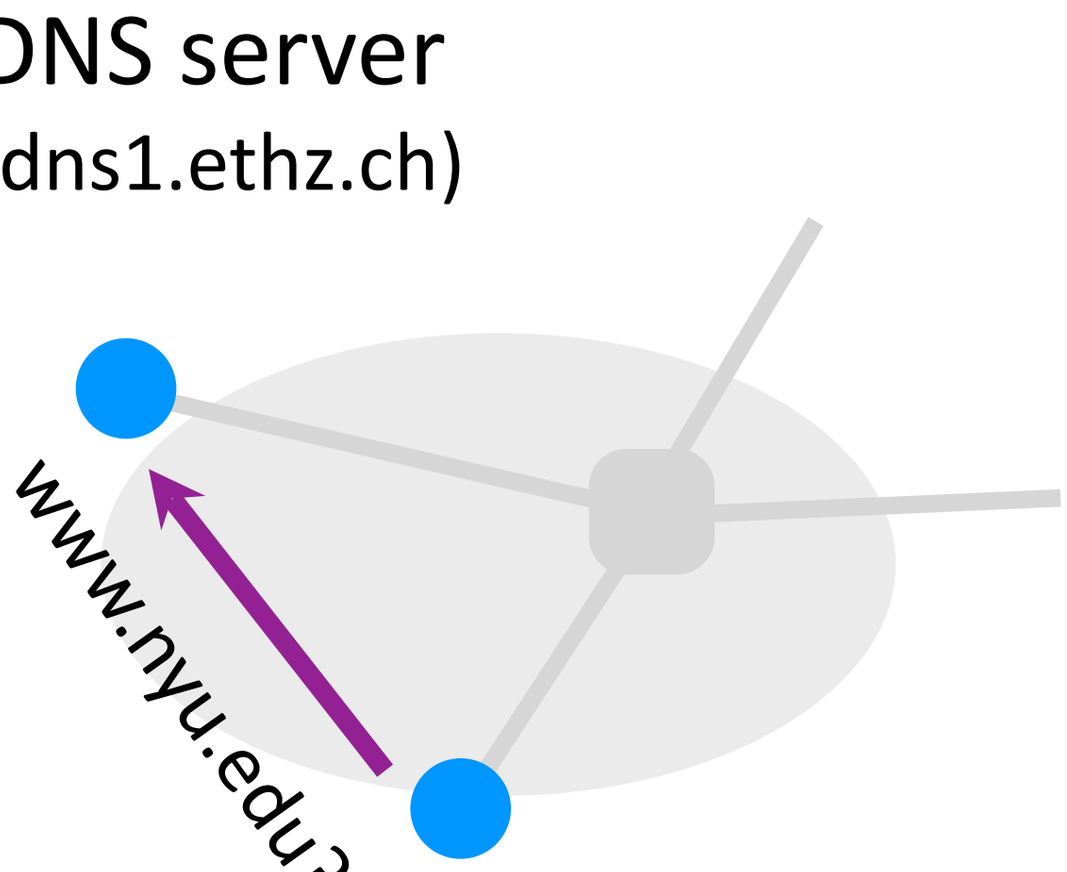
A DNS server stores Resource Records composed of a (name, value, type, TTL)

Records	Name	Value
A	hostname	IP address
NS	domain	DNS server name
MX	domain	Mail server name
CNAME	alias	canonical name
PTR	IP address	corresponding hostname

DNS resolution can either be recursive or iterative

When performing a recursive query,
the client offload the task of resolving to the server

local
DNS server
(dns1.ethz.ch)



DNS client
(me.ee.ethz.ch)

root servers

Where is .edu?
Where is nyu.edu?
.edu servers
Where is www.nyu.edu?
nyu.edu servers
DNS client
(me.ee.ethz.ch)

To reduce resolution times,
DNS relies on caching

DNS servers cache responses to former queries

and your client *and* the applications (!)

Authoritative servers associate a lifetime to each record

Time-To-Live (TTL)

DNS records can only be cached for TTL seconds

after which they must be cleared

As top-level servers rarely change & popular website visited often, caching is very effective (*)

Top 10% of names account for 70% of lookups

9% of lookups are unique

Limit cache hit rate to 91%

Practical cache hit rates ~75%

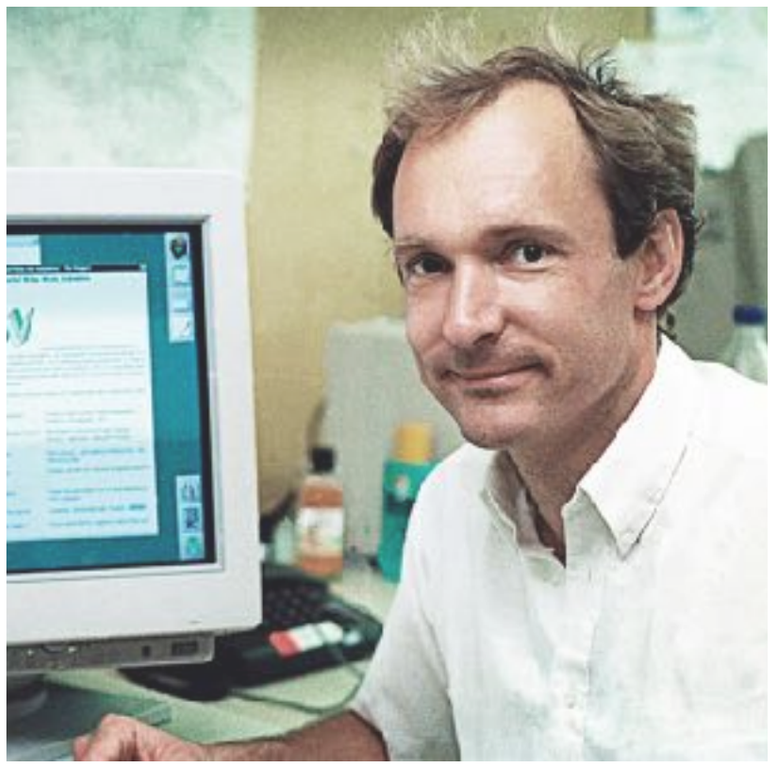
(*) see https://pdos.csail.mit.edu/papers/dns:ton.pdf

DNS

Web

http://www.google.ch

The Web as we know it was founded in ~1990,
by Tim Berners-Lee, physicist at CERN



Tim Berners-Lee Photo: CERN

His goal:

provide distributed access to data

The World Wide Web (WWW):

a distributed database of “pages”
linked together via the
Hypertext Transport Protocol (HTTP)

The Web was and still is so successful as
it enables everyone to self-publish content

Self-publishing on the Web is easy, independent & free

and accessible, to everyone

People weren’t looking for technical perfection

little interest in collaborative or idealistic endeavor

People essentially want to make their mark

and find something neat…

The WWW is made of three key components

Infrastructure	Content	Implementation
Clients/Browser	Objects files, pictures, videos, …	URL: name content
Servers	*organized* in	HTTP: transport content
Proxies	Web sites a collection of objects	

We'll focus on
its implementation

Infrastructure	Content	Implementation
Clients/Browser	Objects files, pictures, videos, …	URL: name content
Servers	*organized* in	HTTP: transport content
Proxies	Web sites a collection of objects	

Infrastructure	Content	Implementation
Clients/Browser	Objects files, pictures, videos, …	**URL: name content**
Servers	*organized* in	HTTP: transport content
Proxies	Web sites a collection of objects	

A Uniform Resource Locator (URL)
refers to an Internet ressource

protocol://hostname[:port]/directory_path/resource

protocol://hostname[:port]/directory_path/resource

HTTP(S)

FTP

SMTP…

protocol://hostname[:port]/directory_path/resource

DNS Name

IP address

default to protocol's standard

HTTP:80, HTTPs:443

protocol://hostname[:port]/directory_path/resource

protocol://hostname[:port]/directory_path/resource

identify the resource
on the destination

Infrastructure

Clients/Browser

Servers

Proxies

Content

Objects
files, pictures, videos, …

organized in

Web sites
a collection of objects

Implementation

URL: name content

HTTP: transport content

HTTP is a rather simple synchronous request/reply protocol

HTTP is layered over a bidirectional byte stream

almost always TCP

HTTP is text-based (ASCII)

human readable, easy to reason about

HTTP is stateless

it maintains *no info* about past client requests

http://

Protocol

Performance

Allow (list of methods supported)

Content encoding (*e.g.*, gzip)

Content-Length

Content-Type

Expires (caching)

Last-Modified (caching)

HTTP is a stateless protocol,
meaning each request is treated independently

advantages

server-side scalability

failure handling is trivial

disadvantages

some applications need state!

(shopping cart, user profiles, tracking)

How can you maintain state in a stateless protocol?

HTTP makes the client maintain the state.

This is what the so-called cookies are for!

client stores small state

on behalf of the server *X*

client sends state

in all future requests to *X*

can provide authentication

telnet google.ch 80

request

```
GET / HTTP/1.1
Host: www.google.ch
```

answer

```
HTTP/1.1 200 OK
Date: Sun, 01 May 2016 14:10:30 GMT
Cache-Control: private, max-age=0
Content-Type: text/html; charset=ISO-8859-1

Protocol

Performance

Performance goals vary depending on who you ask

	User	Network operators	Content provider
			
wish	fast downloads high availability	no overload	happy users cost-effective infrastructure
solution	Improve HTTP to compensate for TCP weakspots	Caching and Replication	

User

wish

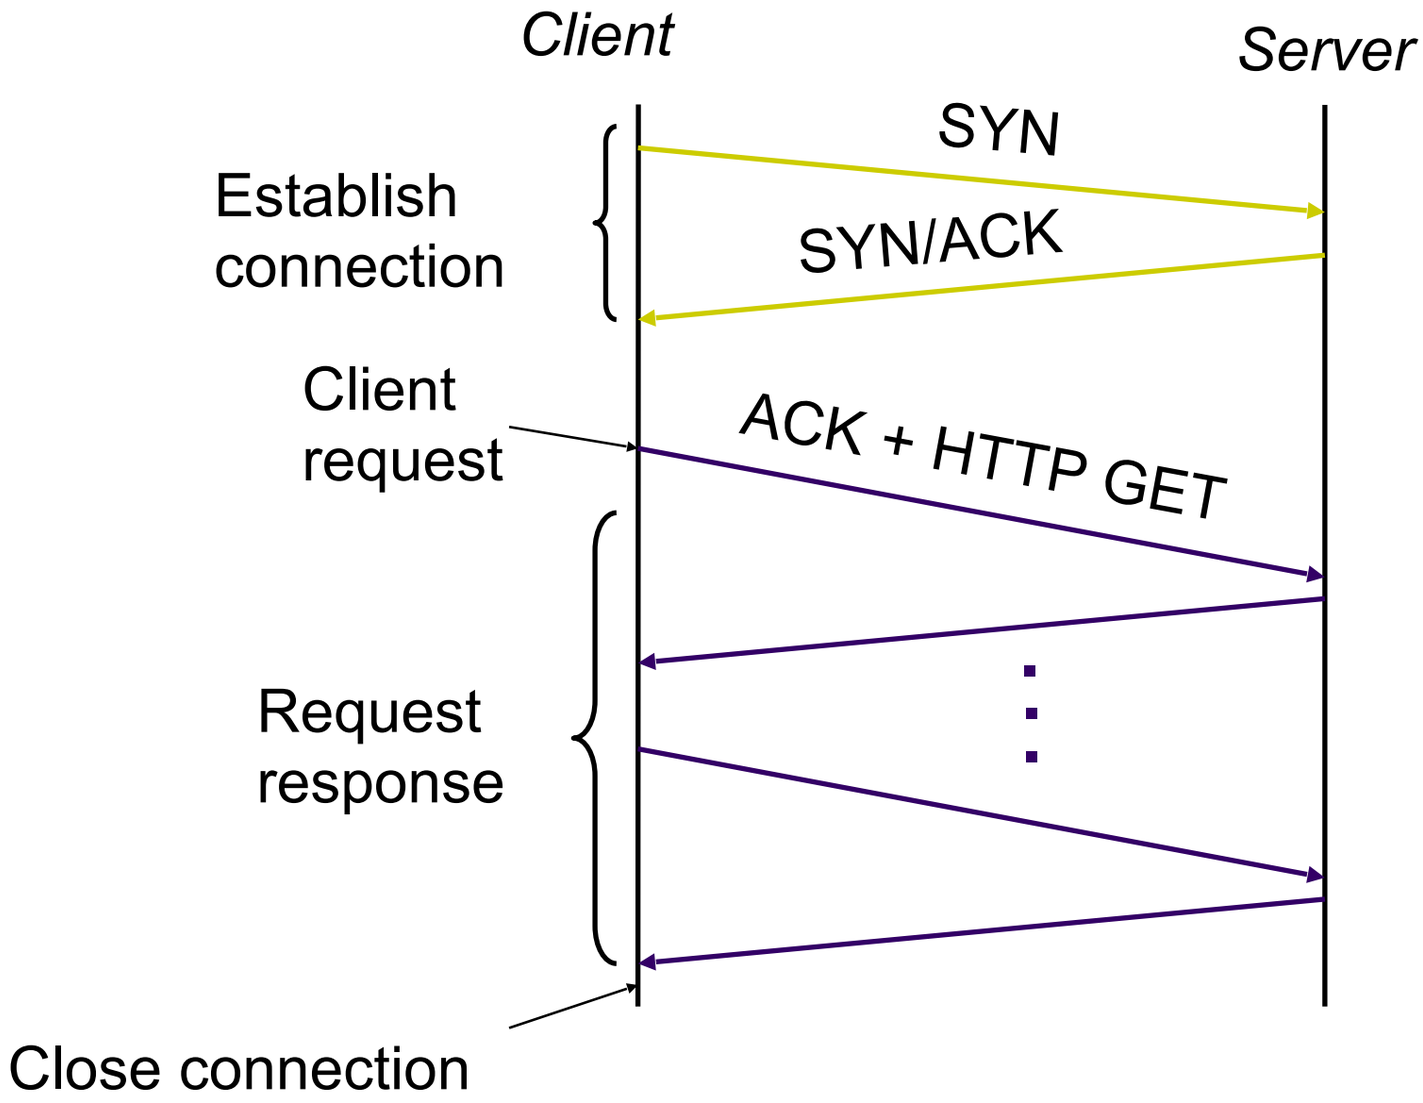
fast downloads

high availability

solution

Improve HTTP to compensate for TCP weakspots

Relying on TCP forces a HTTP client to open a connection before exchanging anything



Most Web pages have multiple objects,
naive HTTP opens one TCP connection for each…

Fetching *n* objects requires ~*2n* RTTs

TCP establishment

HTTP request/response

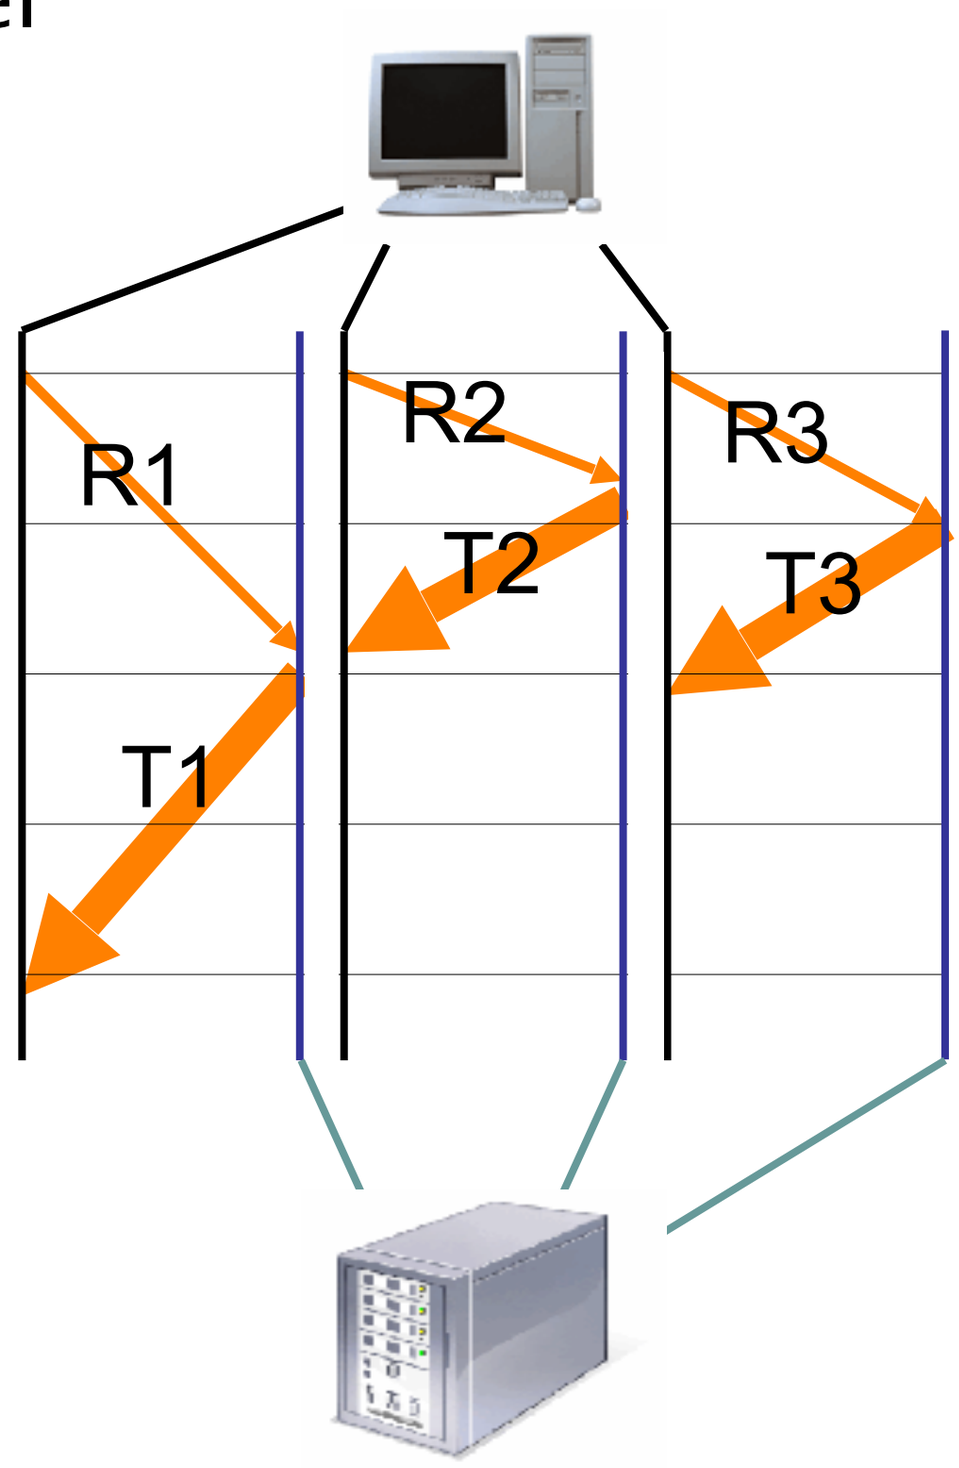
One solution to that problem is to use multiple TCP connections in parallel

User Happy!

Content provider Happy!

Network operator Not Happy!

Why?



Another solution is to use persistent connections across multiple requests, default in HTTP/1.1

Avoid overhead of connection set-up and teardown

clients or servers can tear down the connection

Allow TCP to learn more accurate RTT estimate

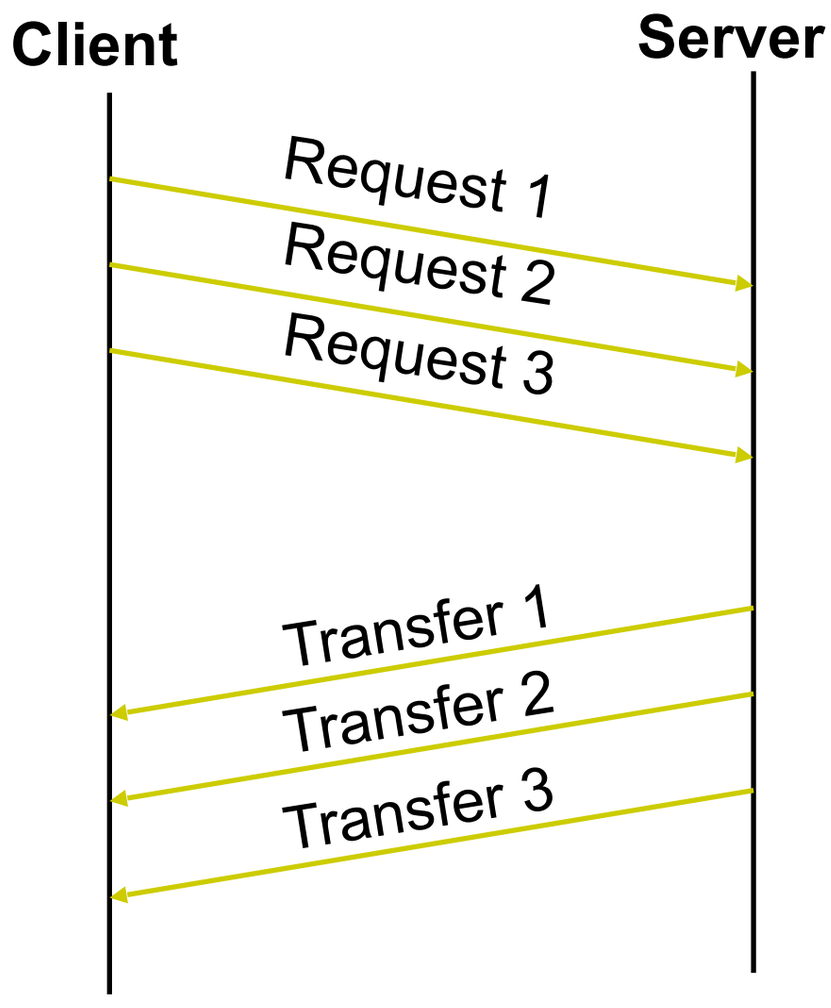
and with it, more precise timeout value

Allow TCP congestion window to increase

and therefore to leverage higher bandwidth

Yet another solution is to pipeline requests & replies asynchronously, on one connection

- batch requests and responses to reduce the number of packets
- multiple requests can be packed into one TCP segment



Considering the time to retrieve *n* small objects, pipelining wins

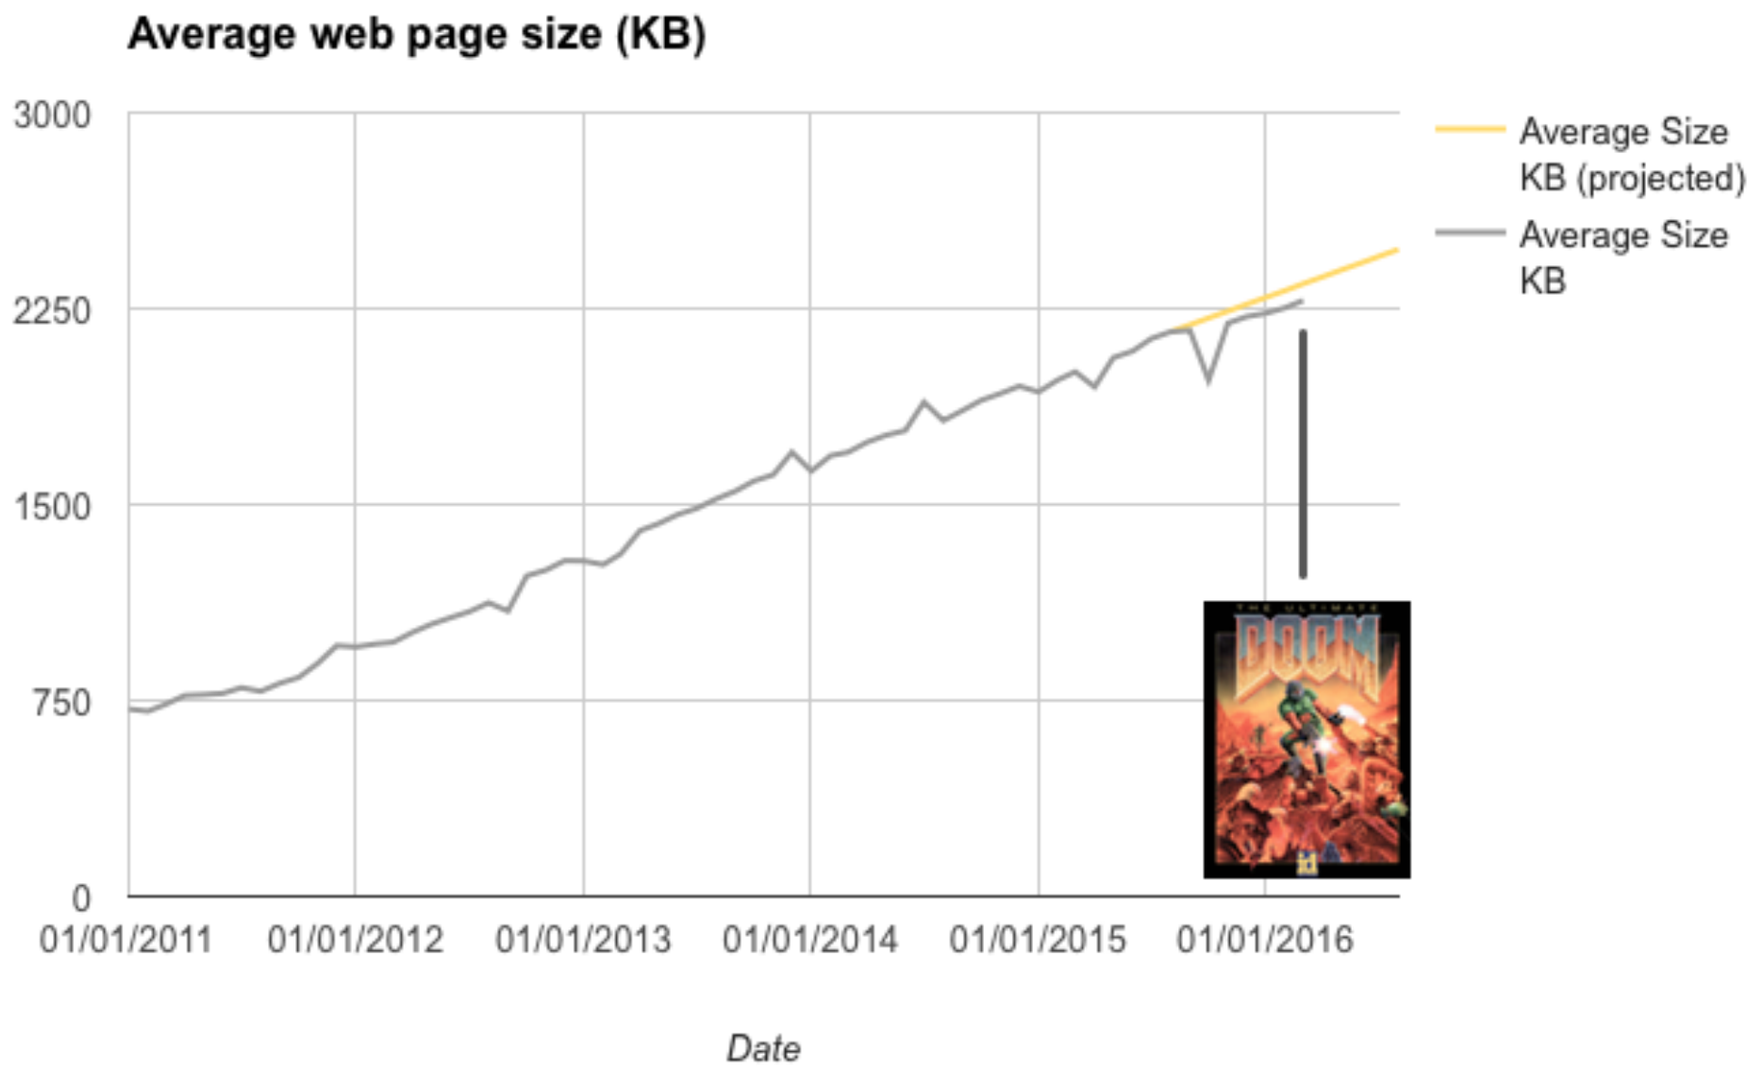
	# RTTS
one-at-a-time	~2*n*
M concurrent	~2*n*/M
persistent	~*n*+1
pipelined	2

Considering the time to retrieve *n* big objects,
there is no clear winners as bandwidth matters more

$$\frac{\#\ \text{RTTS}}{} \qquad \frac{\sim n * \text{avg. file size}}{\text{bandwidth}}$$

Today, the average webpage size is 2.3 MB

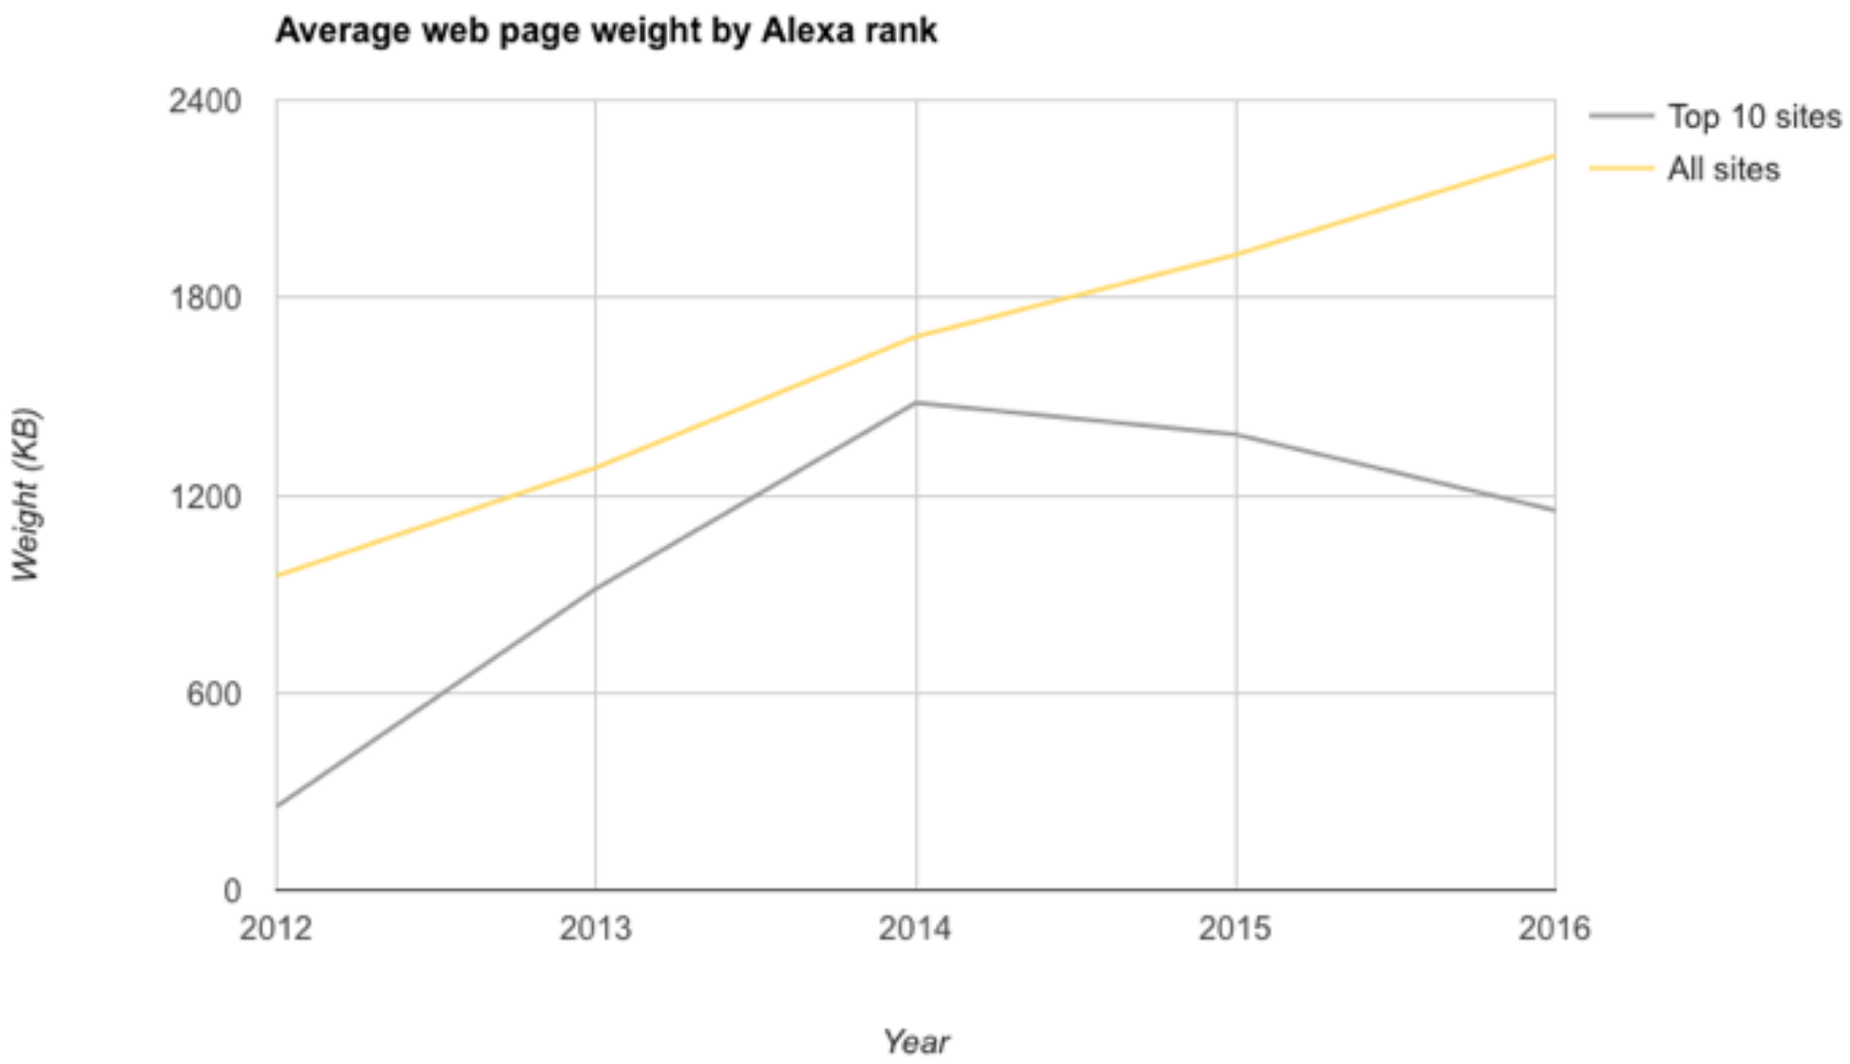
as much as the original DOOM game…



(*) see https://mobiforge.com/research-analysis/the-web-is-doom

Top web sites have decreased in size though

because they care about TCP performance



(*) see https://mobiforge.com/research-analysis/the-web-is-doom

User

Network operators

Content provider

wish

no overload

happy users

cost-effective infrastructure

solution

Caching and Replication

Caching leverages the fact that
highly popular content largely overlaps

Just think of how many times
you request the facebook logo
per day

vs

how often it *actually* changes

Caching it save time for your browser
and decrease network and server load

Yet, a significant portion of
the HTTP objects are “uncachable"

Examples		
	dynamic data	stock prices, scores, ...
	scripts	results based on parameters
	cookies	results may be based on passed data
	SSL	cannot cache encrypted data
	advertising	wants to measure # of hits ($$$)

To limit staleness of cached objects,
HTTP enables a client to validate cached objects

Server hints when an object expires (kind of TTL)

as well as the last modified date of an object

Client conditionally requests a ressources

using the “if-modified-since” header in the HTTP request

Server compares this against “last modified” time

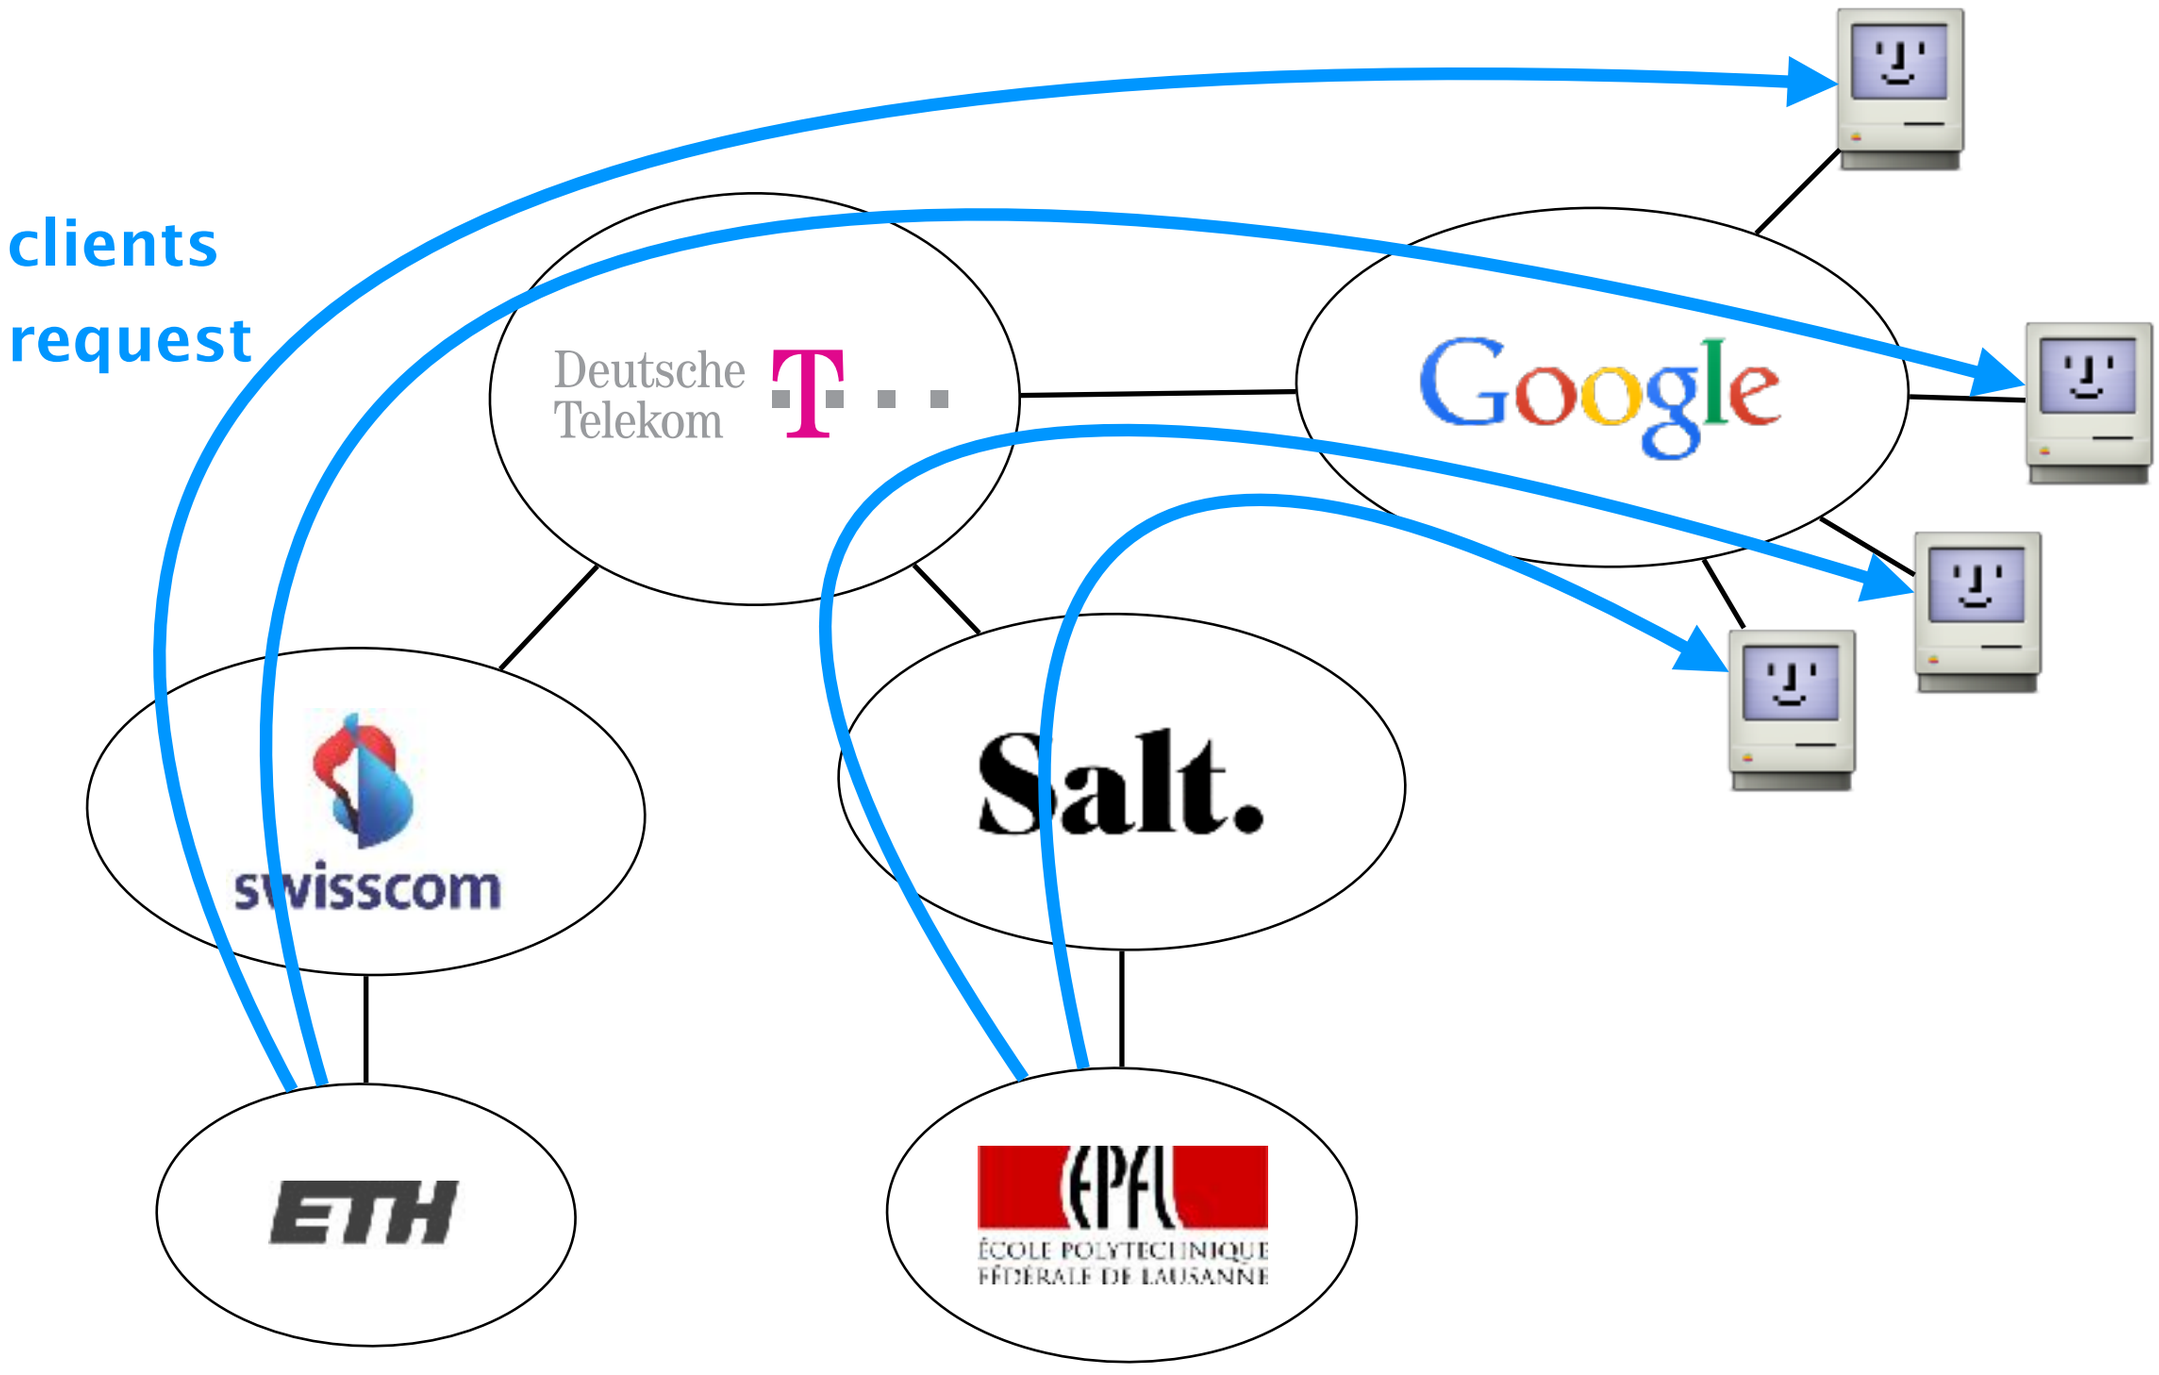
of the resource and returns:

- Not Modified if the resource has not changed
- OK with the latest version

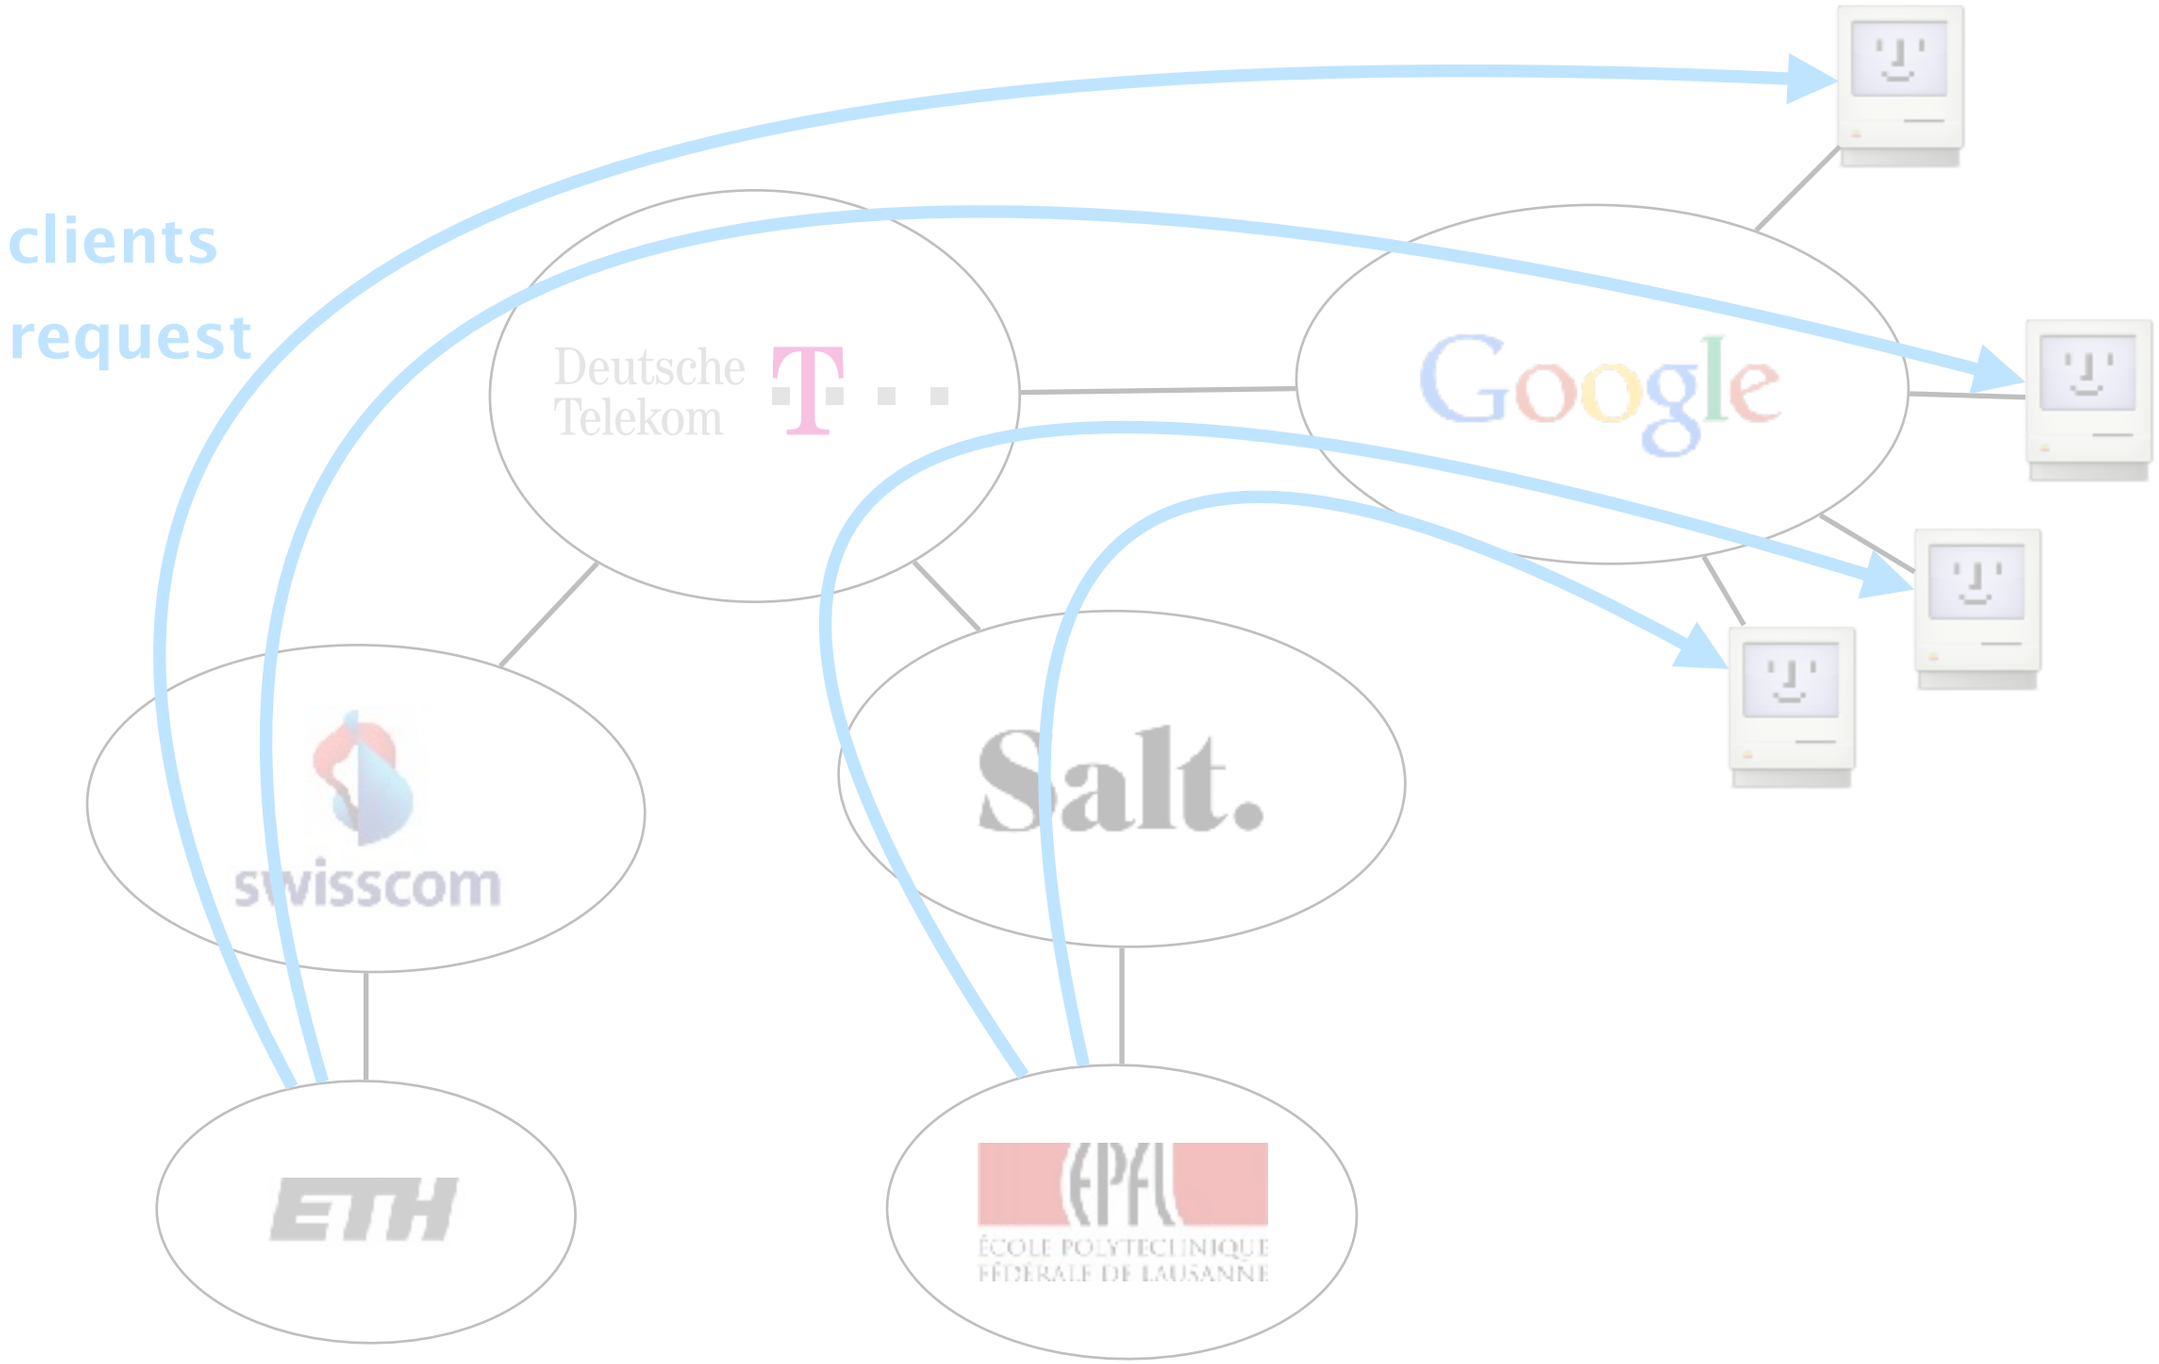
Caching can and is performed at different locations

client	browser cache
close to the client	forward proxy Content Distribution Network (CDN)
close to the destination	reverse proxy

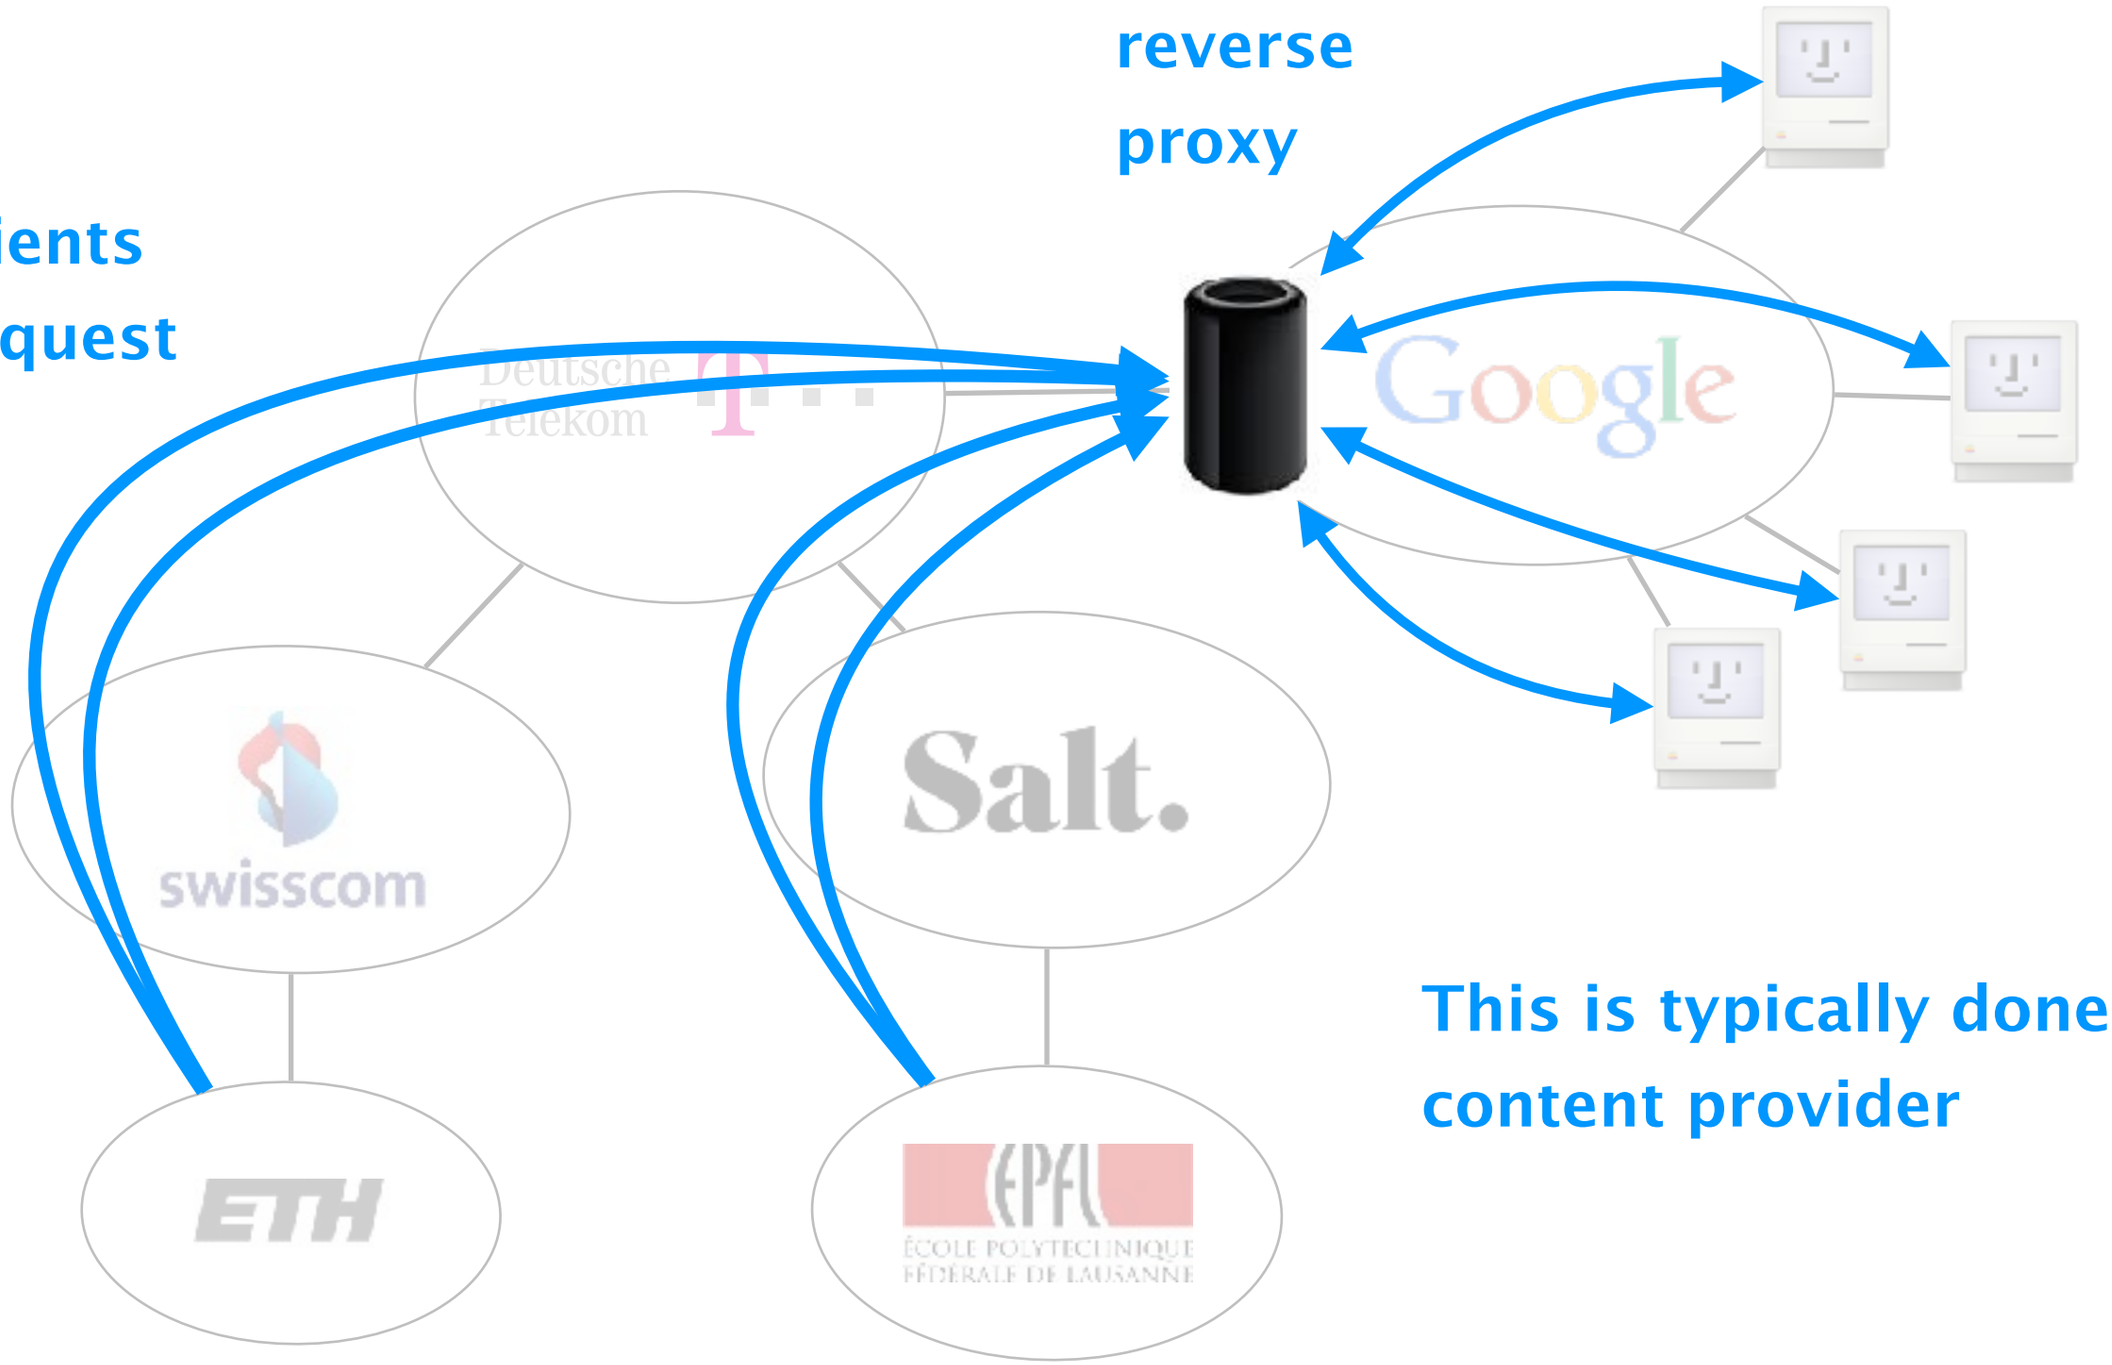
Many clients request the same information



This increases servers and network's load,
while clients experience unnecessary delays

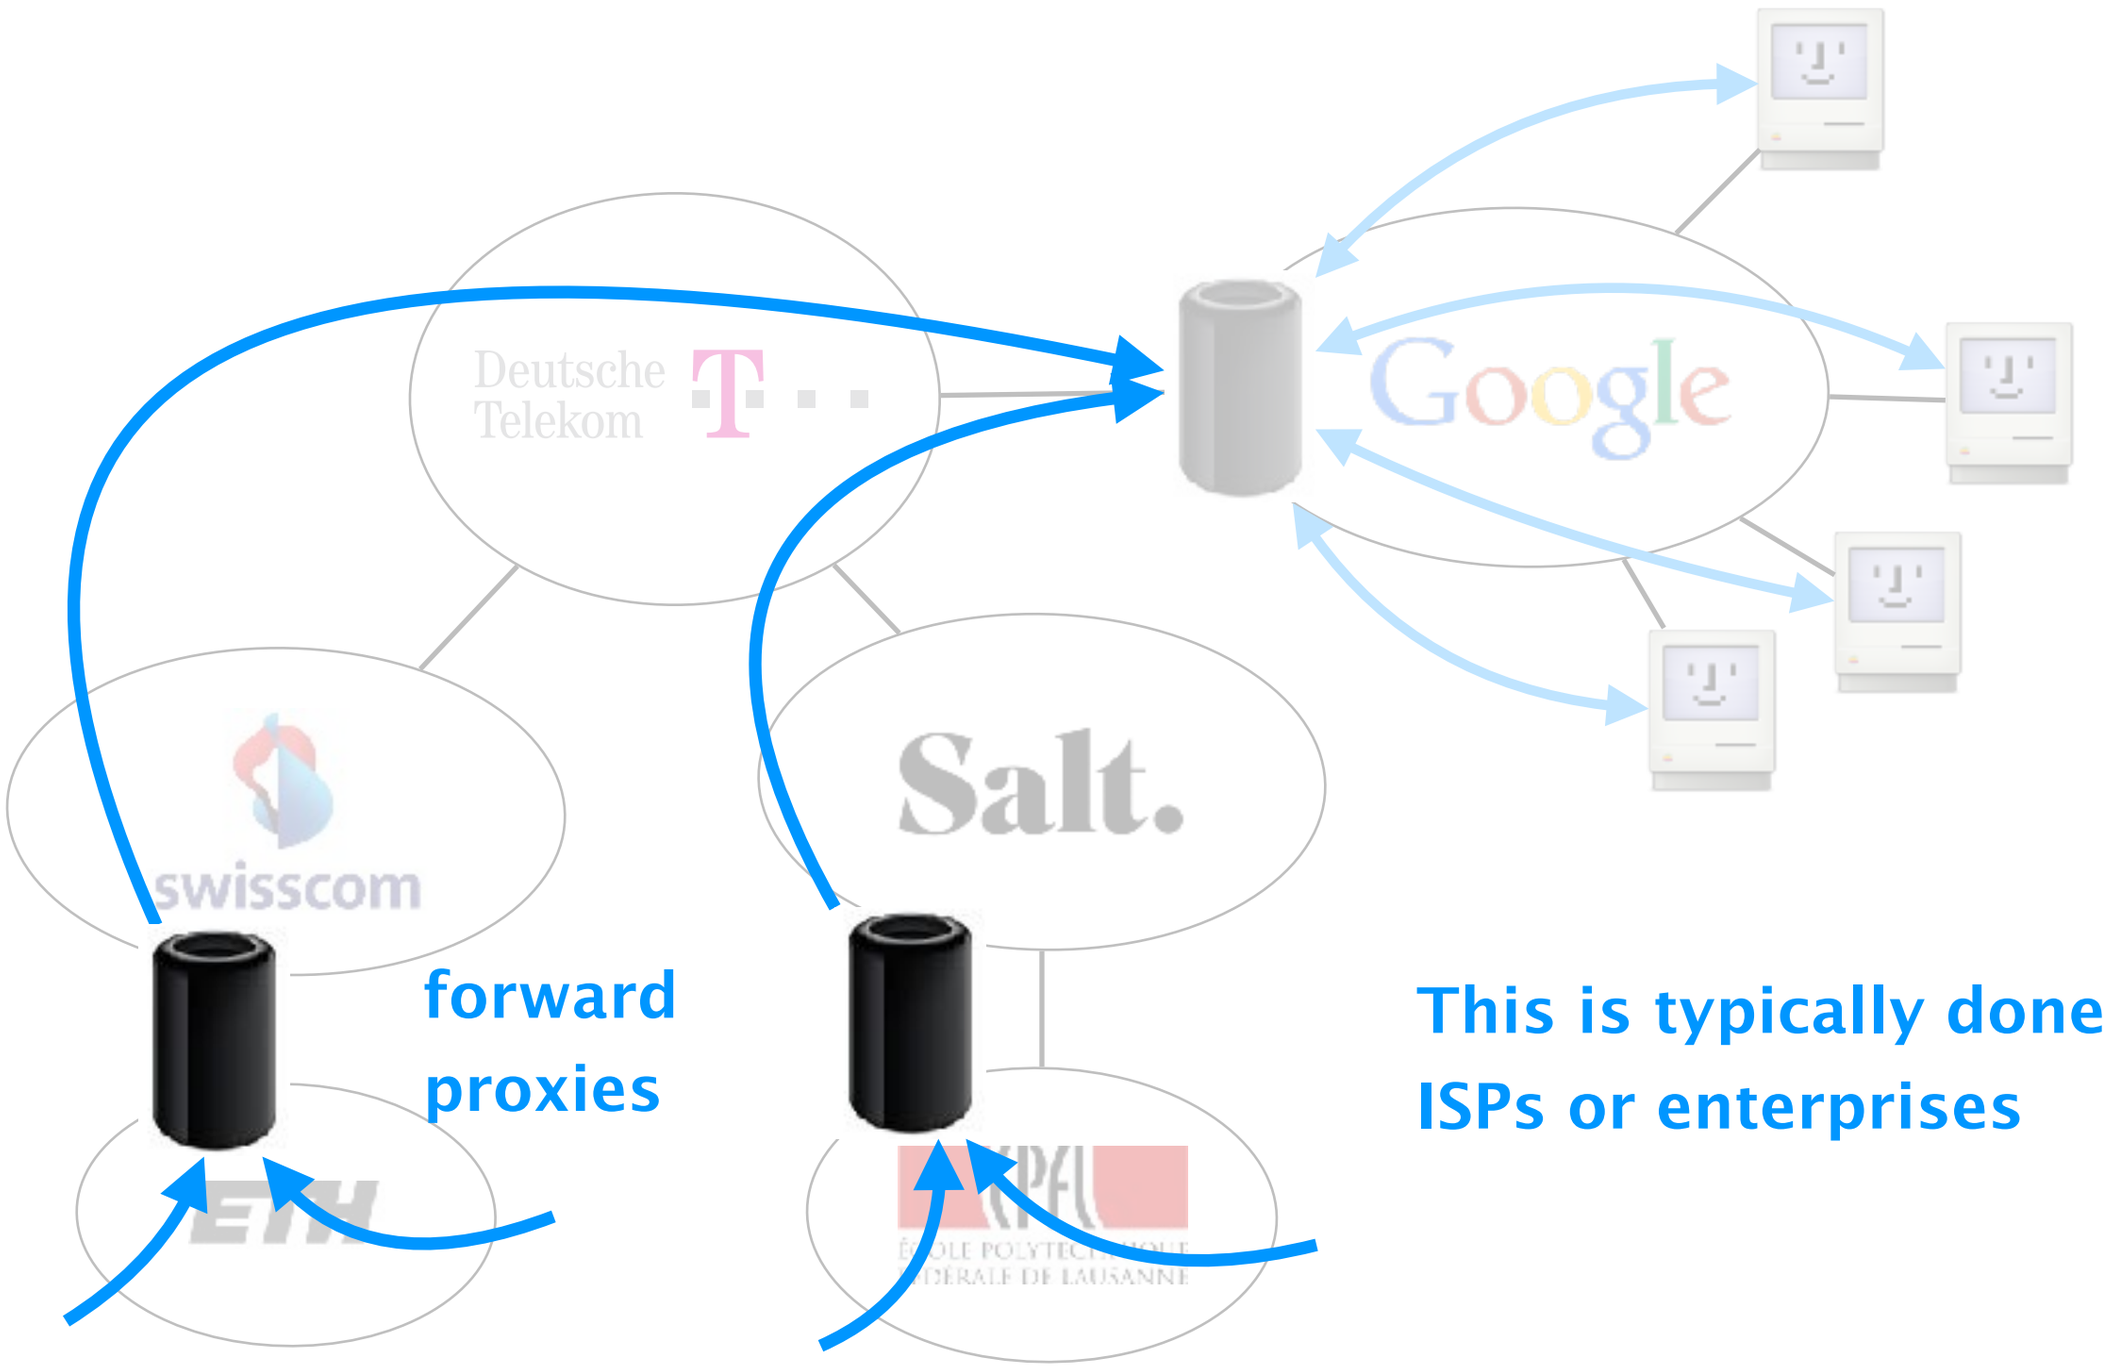


Reverse proxies cache documents close to servers, decreasing their load



This is typically done by content provider

Forward proxies cache documents close to clients, decreasing network traffic, server load and latencies



Network operators

Content provider

wish

no overload

happy users

cost-effective infrastructure

solution

Caching and Replication

The idea behind replication is to duplicate popular content all around the globe

Spreads load on server

e.g., across multiple data-centers

Places content closer to clients

only way to beat the “speed-of-light”

Helps speeding up uncachable content

still have to pull it, but from closer

The problem of CDNs is to direct and serve your requests from a close, non-overloaded replica

DNS-based

returns ≠ IP addresses

based on

- client geo-localization
- server load

BGP Anycast

advertise the same IP prefix from different locations

avoided in practice,
any idea why?

Akamai is one of the largest CDNs in the world, boasting servers in more than 20,000 locations

http://wwwnui.akamai.com/gnet/globe/index.html

Akamai uses a combination of

- *pull* caching

  direct result of clients requests

- *push* replication

  when expecting high access rate

together with some dynamic processing

dynamic Web pages, transcoding,…

“Akamaizing” content is easily done by modifying content to reference the Akamai’s domains

Akamai creates domain names for each client

a128.g.akamai.net for cnn.com

Client modifies its URL to refer to Akamai’s domain

http://www.cnn.com/image-of-the-day.gif

becomes

http://a128.g.akamai.net/image-of-the-day.gif

Requests are now sent to the CDN infrastructure

Communication Networks

Spring 2018

Laurent Vanbever

nsg.ee.ethz.ch

ETH Zürich (D-ITET)

May 14 2018
