Last week on
Communication Networks

How do **local** computers communicate?

Communication Networks

Part 2: The Link Layer

- #1 What is a link?
- #2 How do we identify link adapters?
- #3 How do we share a network medium?
- #4 What is Ethernet?
- #5 How do we interconnect segments at the link layer?

Communication Networks

Part 2: The Link Layer

What is a link?

#2

How do we identify link adapters?

How do we share a network medium?

What is Ethernet?

How do we interconnect segments at the link layer?

MAC addresses...

identify the sender & receiver adapters
used within a link

are uniquely assigned
hard-coded into the adapter when built

use a flat space of 48 bits
allocated hierarchically

Why don't we simply use IP addresses?

Links can support any protocol (not just IP)
different addresses on different kind of links

Adapters may move to different locations
cannot assign static IP address, it has to change

Adapters must be identified during bootstrap
need to talk to an adapter to give it an IP address

You need to solve two problems when you bootstrap an adapter

Who am I?

MAC-to-IP binding

How do I acquire an IP address?

Who are you?

IP-to-MAC binding

Given an IP address reachable on a link,
How do I find out what MAC to use?

Who am I?

MAC-to-IP binding

How do I acquire an IP address?

Dynamic Host Configuration Protocol

Who are you?

IP-to-MAC binding

Given an IP address reachable on a link,

How do I find out what MAC to use?

Address Resolution Protocol

Communication Networks

Part 2: The Link Layer

What is a link?

How do we identify link adapters?

#3

How do we share a network medium?

What is Ethernet?

How do we interconnect segments at the link layer?

Essentially, there are three techniques to deal with Multiple Access Control (MAC)

Divide the channel into pieces
either in time or in frequency

Take turns
pass a token for the right to transmit

Random access
allow collisions, detect them and then recover

This week on
Communication Networks

Link Layer

The diagram consists of two orange rectangular boxes. The box on the left is labeled 'Link Layer' and 'The End' below it. The box on the right is labeled 'Network Layer' and 'The Beginning' below it. The boxes are positioned side-by-side, with the 'Link Layer' box on the left and the 'Network Layer' box on the right.

The End

Network Layer

The Beginning

Link Layer

Network Layer

The End

The Local Area Networks we have considered so far
define **single broadcast domains**

If one user broadcast a frame,
every other user receives it

As the network scales,
network operators like to segment their LANs

Why?

Improves security

smaller attack surface (visibility & injection)

Improves performance

limit the overhead of broadcast traffic (e.g. ARP)

Improves logistics

separates traffic by role (e.g. staff, students, visitors)

Organizational changes are too frequent to segment networks purely **physically**—rewiring is a major pain

What about doing this in software though?

Enters “Virtual Local Area Networks” (VLANs)

Definition

A VLAN logically identifies a set of ports attached to one (or more) Ethernet switches, forming one broadcast domain

A VLAN identifies a set of ports attached to one or more Ethernet switches

Switches need configuration tables telling them which VLANs are accessible via which interfaces

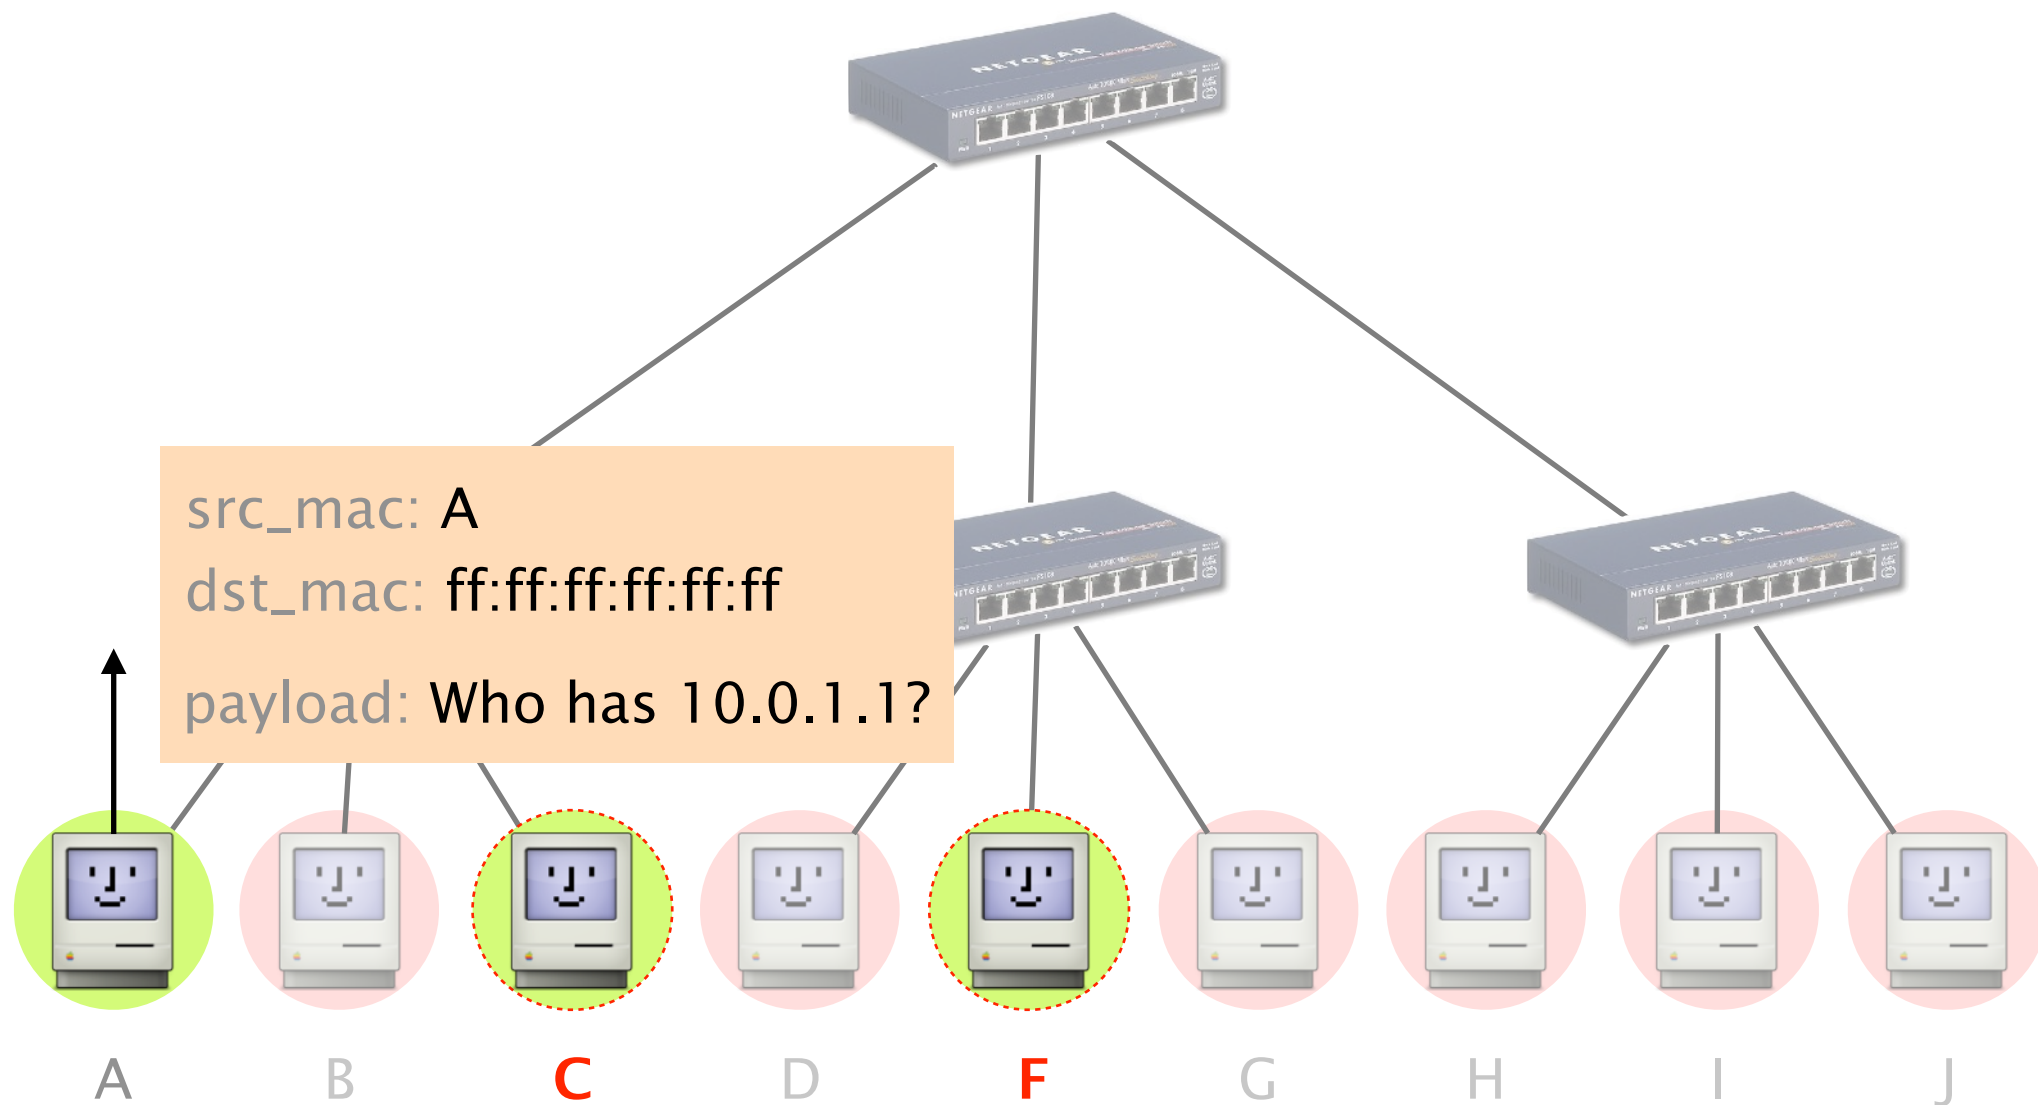

Switches need configuration tables telling them which VLANs are accessible via which interfaces

Consider that A sends a broadcast frame
say, an ARP request

That frame should be received by all staff members:
i.e. C and F, and *only* them

src_mac: A

dst_mac: ff:ff:ff:ff:ff:ff

payload: Who has 10.0.1.1?

How does this switch know
where to flood it next?

e.g. pointless to send it right

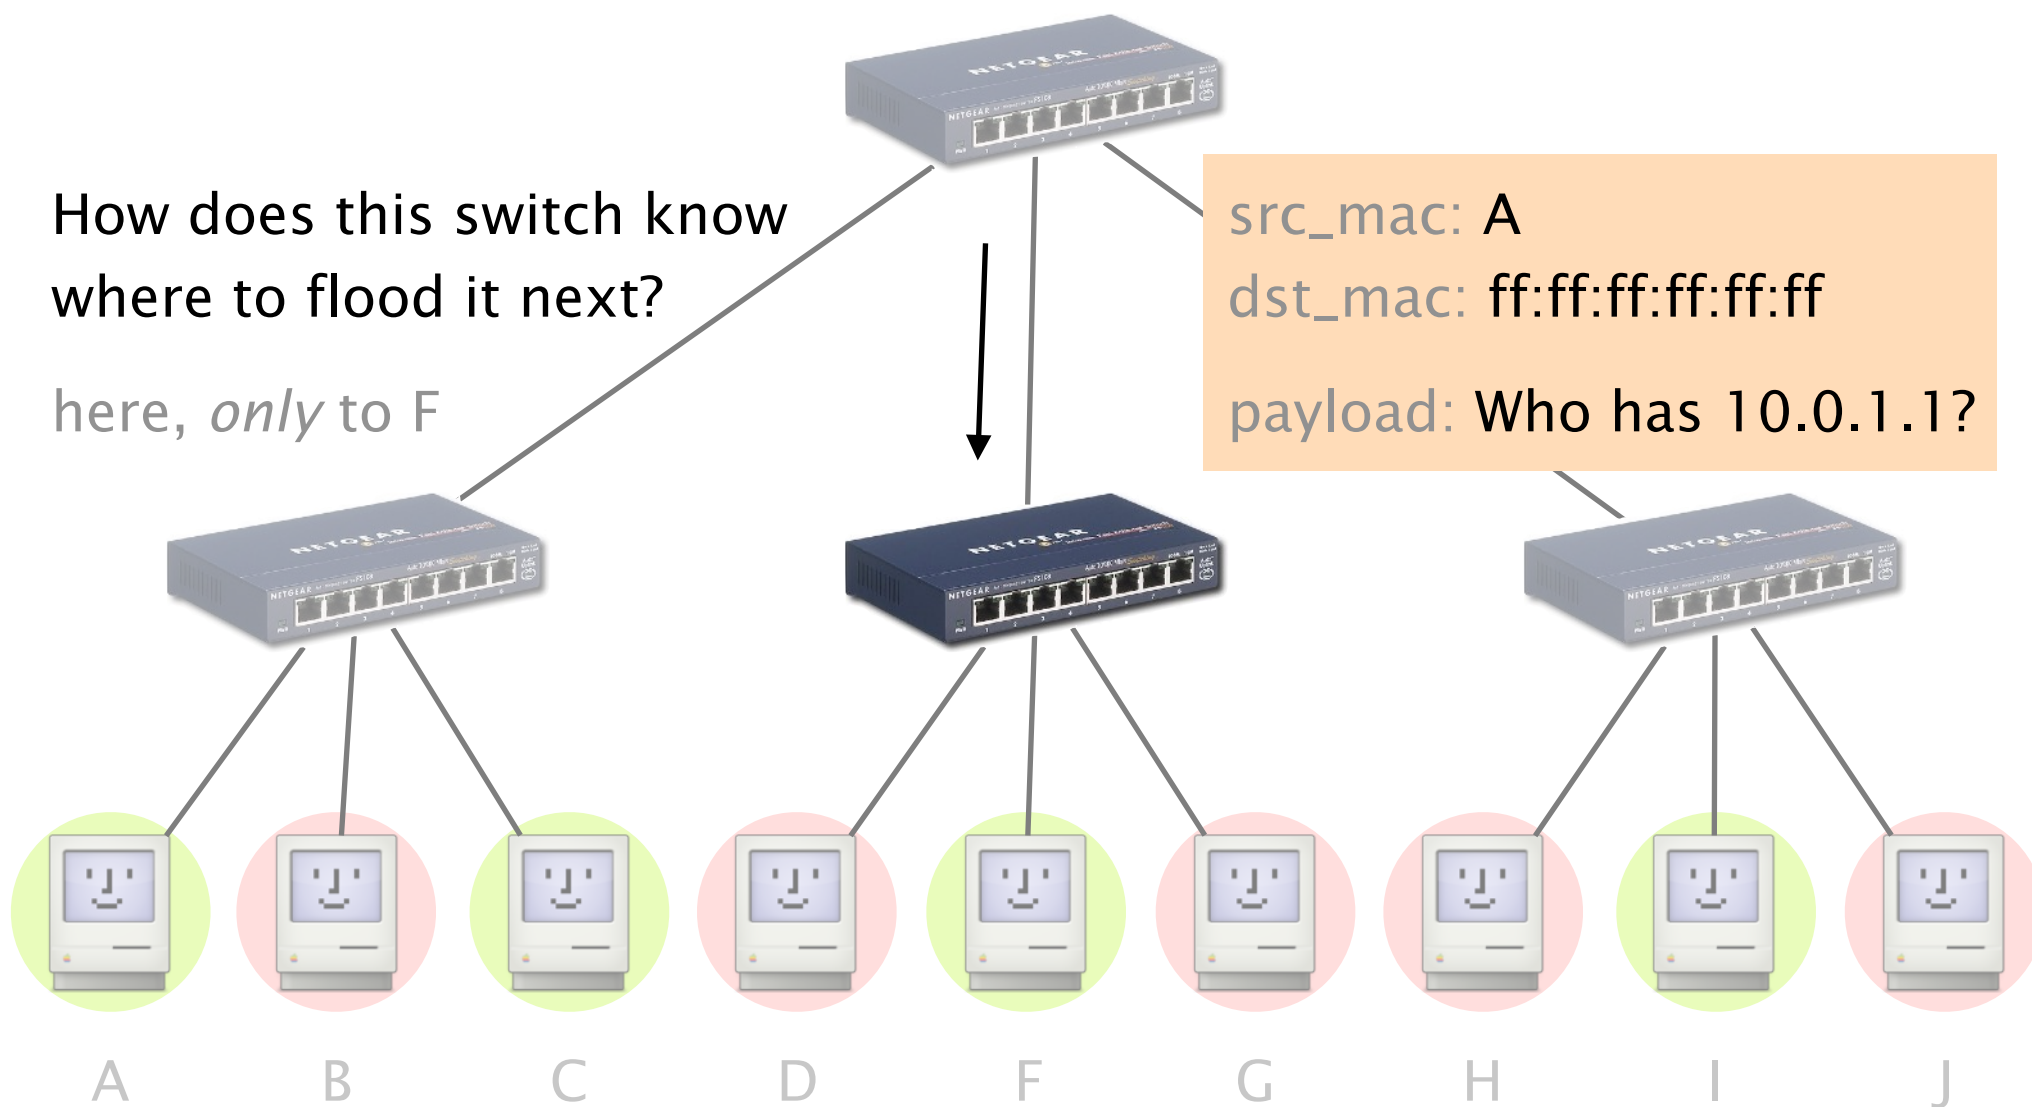

How does this switch know
where to flood it next?

here, *only* to F

src_mac: A

dst_mac: ff:ff:ff:ff:ff:ff

payload: Who has 10.0.1.1?

To identify VLAN, switches add new header when forwarding traffic to another switch

Without VLAN

With VLAN

802.1q Header (4 bytes)
(4 bits missing)

With VLANs, Ethernet links are divided in two sets:
access and trunks (inter switches) links

Access links belong to one VLAN
they do not carry 802.1q headers

Trunk links carry traffic for more than one VLAN
and as such carry 801.1q tagged frames

Each switch runs
one MAC learning algorithm for each VLAN

When a switch receives a frame with
an unknown or a broadcast destination,

it forwards it over all the ports that
belong to the same VLAN

When a switch learns a source address on a port

it associates it to the VLAN of this port and
only uses it when forwarding frames on this VLAN

VLAN "Staff" ●
port 1: A, C port 2: F

VLAN "Student" ●
port 1: B port 2: D,G
port 3: H, I, J

src_mac: A
dst_mac: ff:ff:ff:ff:ff:ff
VID: ●
payload: Who has 10.0.1.1?

Switches can also compute per-VLAN spanning-tree allowing a distinct SPT for each VLAN

allow the operators to use more of their links

root switch
for all VLANs

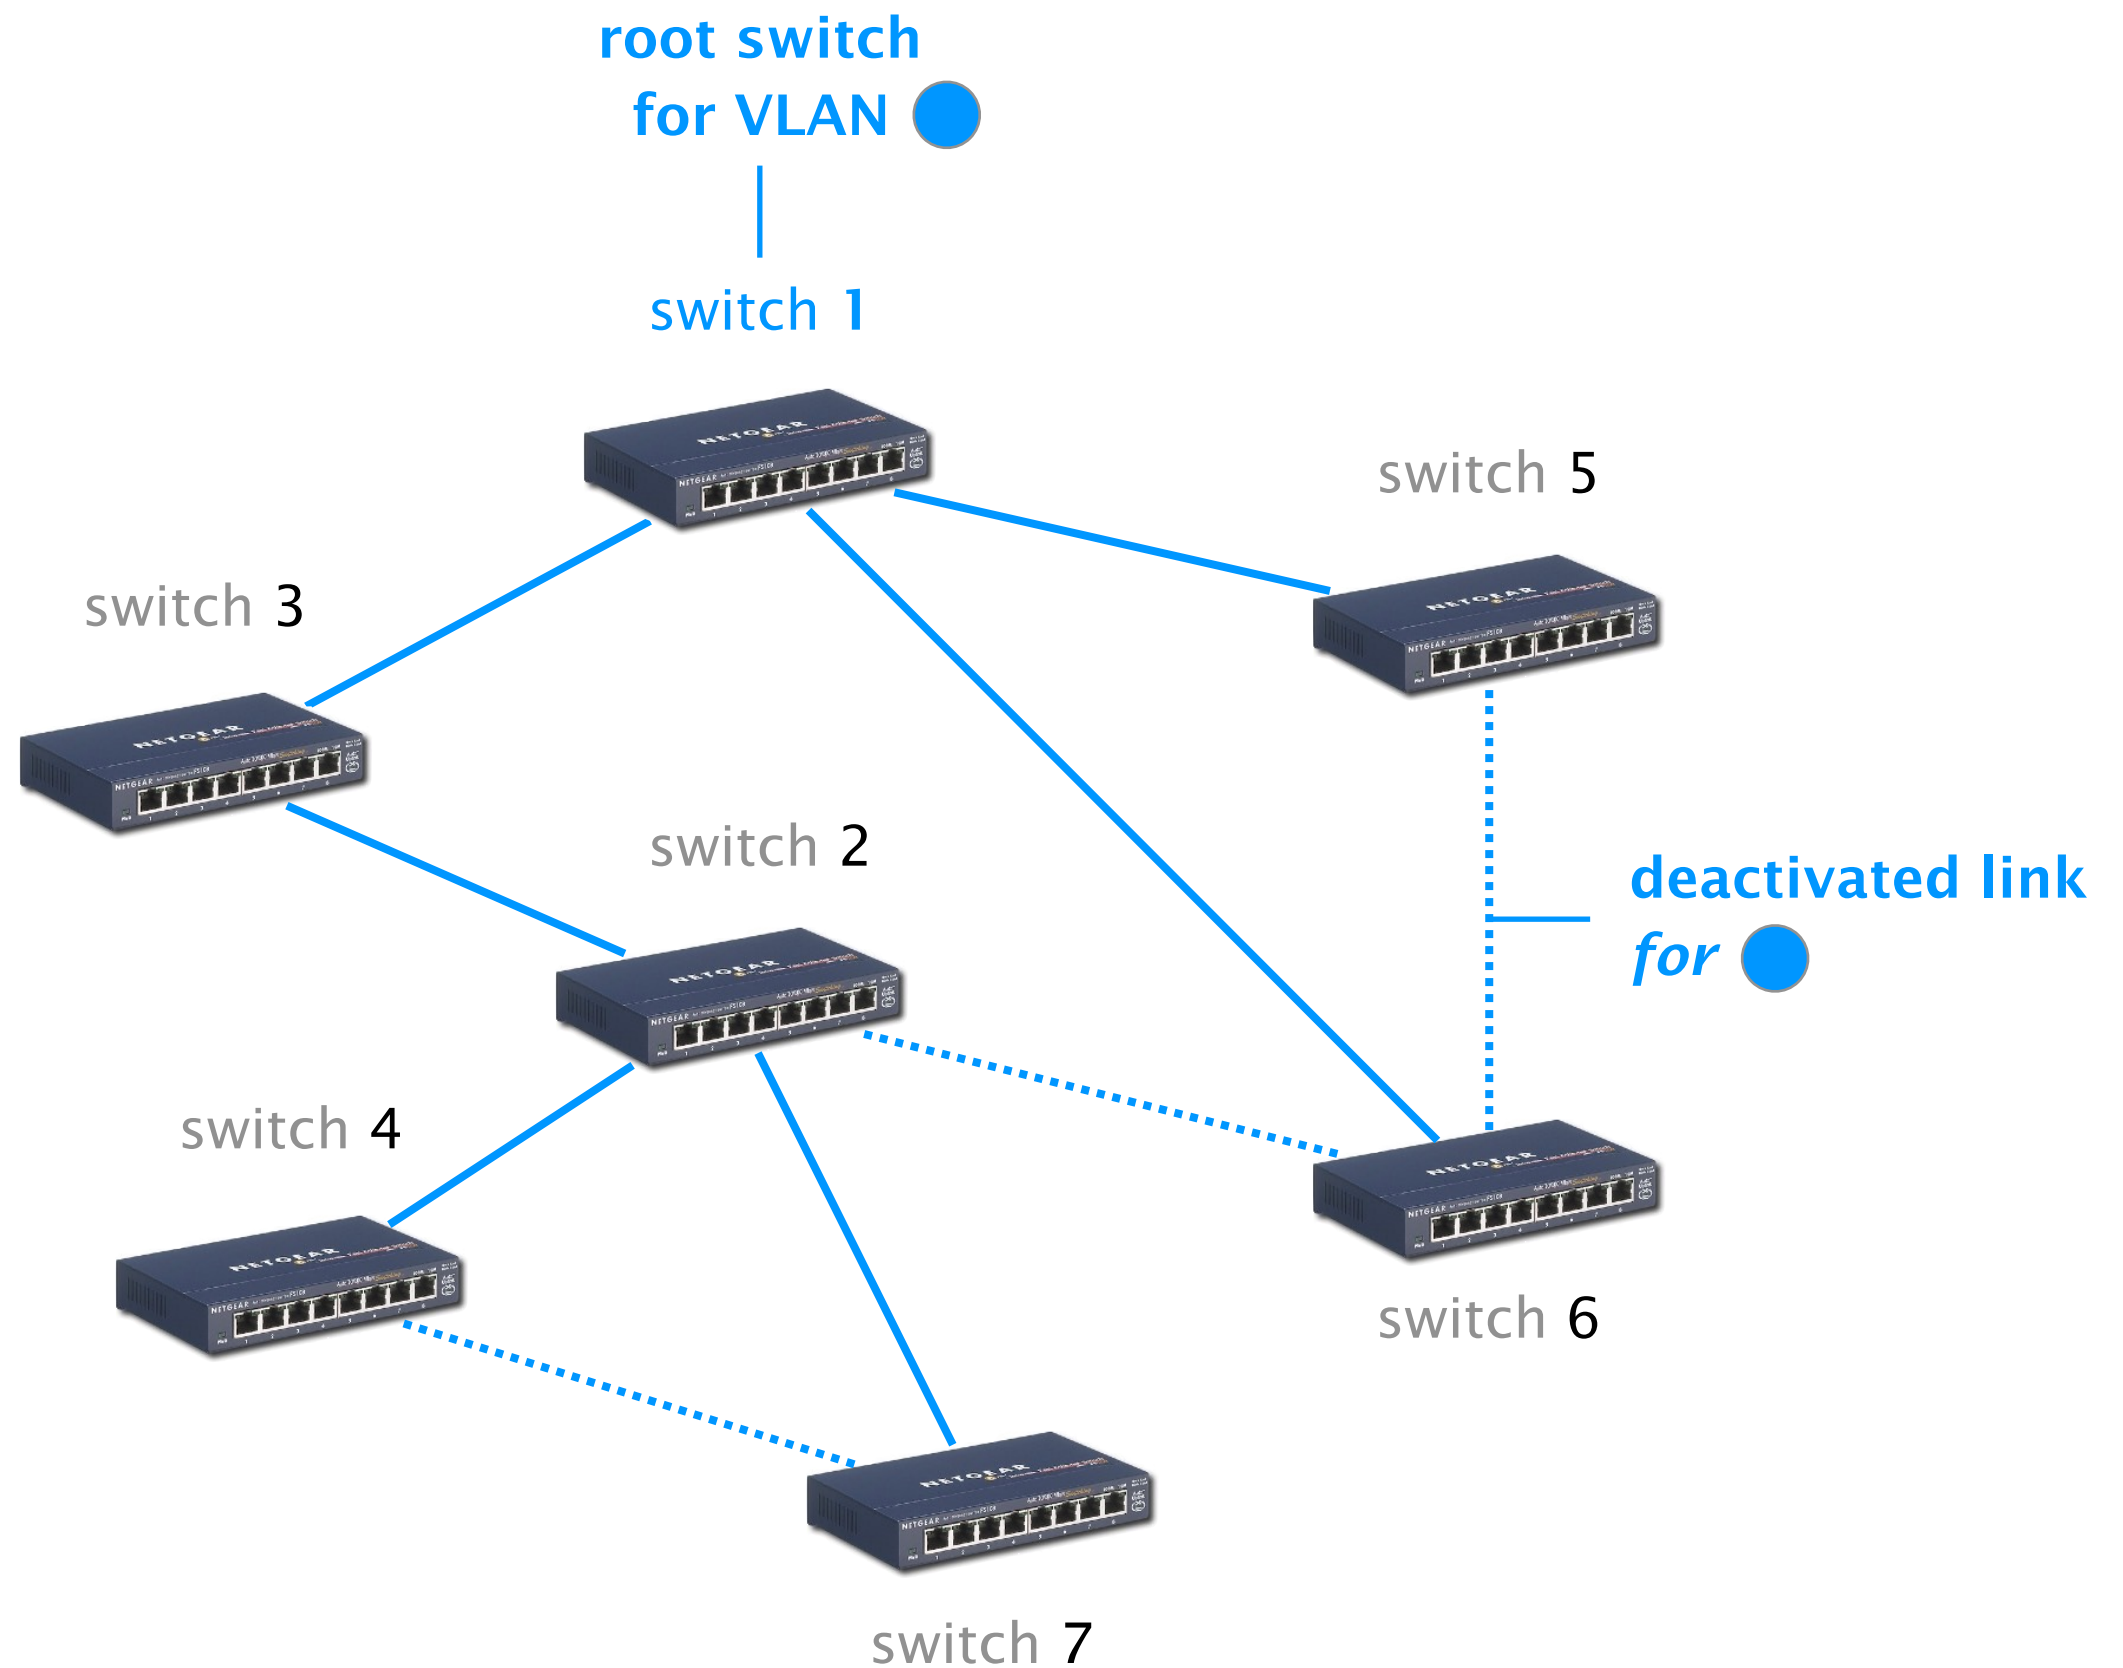

switch 1

Any communication between the red hosts on switch 5 and 6 need to go via switch 1...

Now any communication between the red hosts on switch 5 and 6 go via the direct link

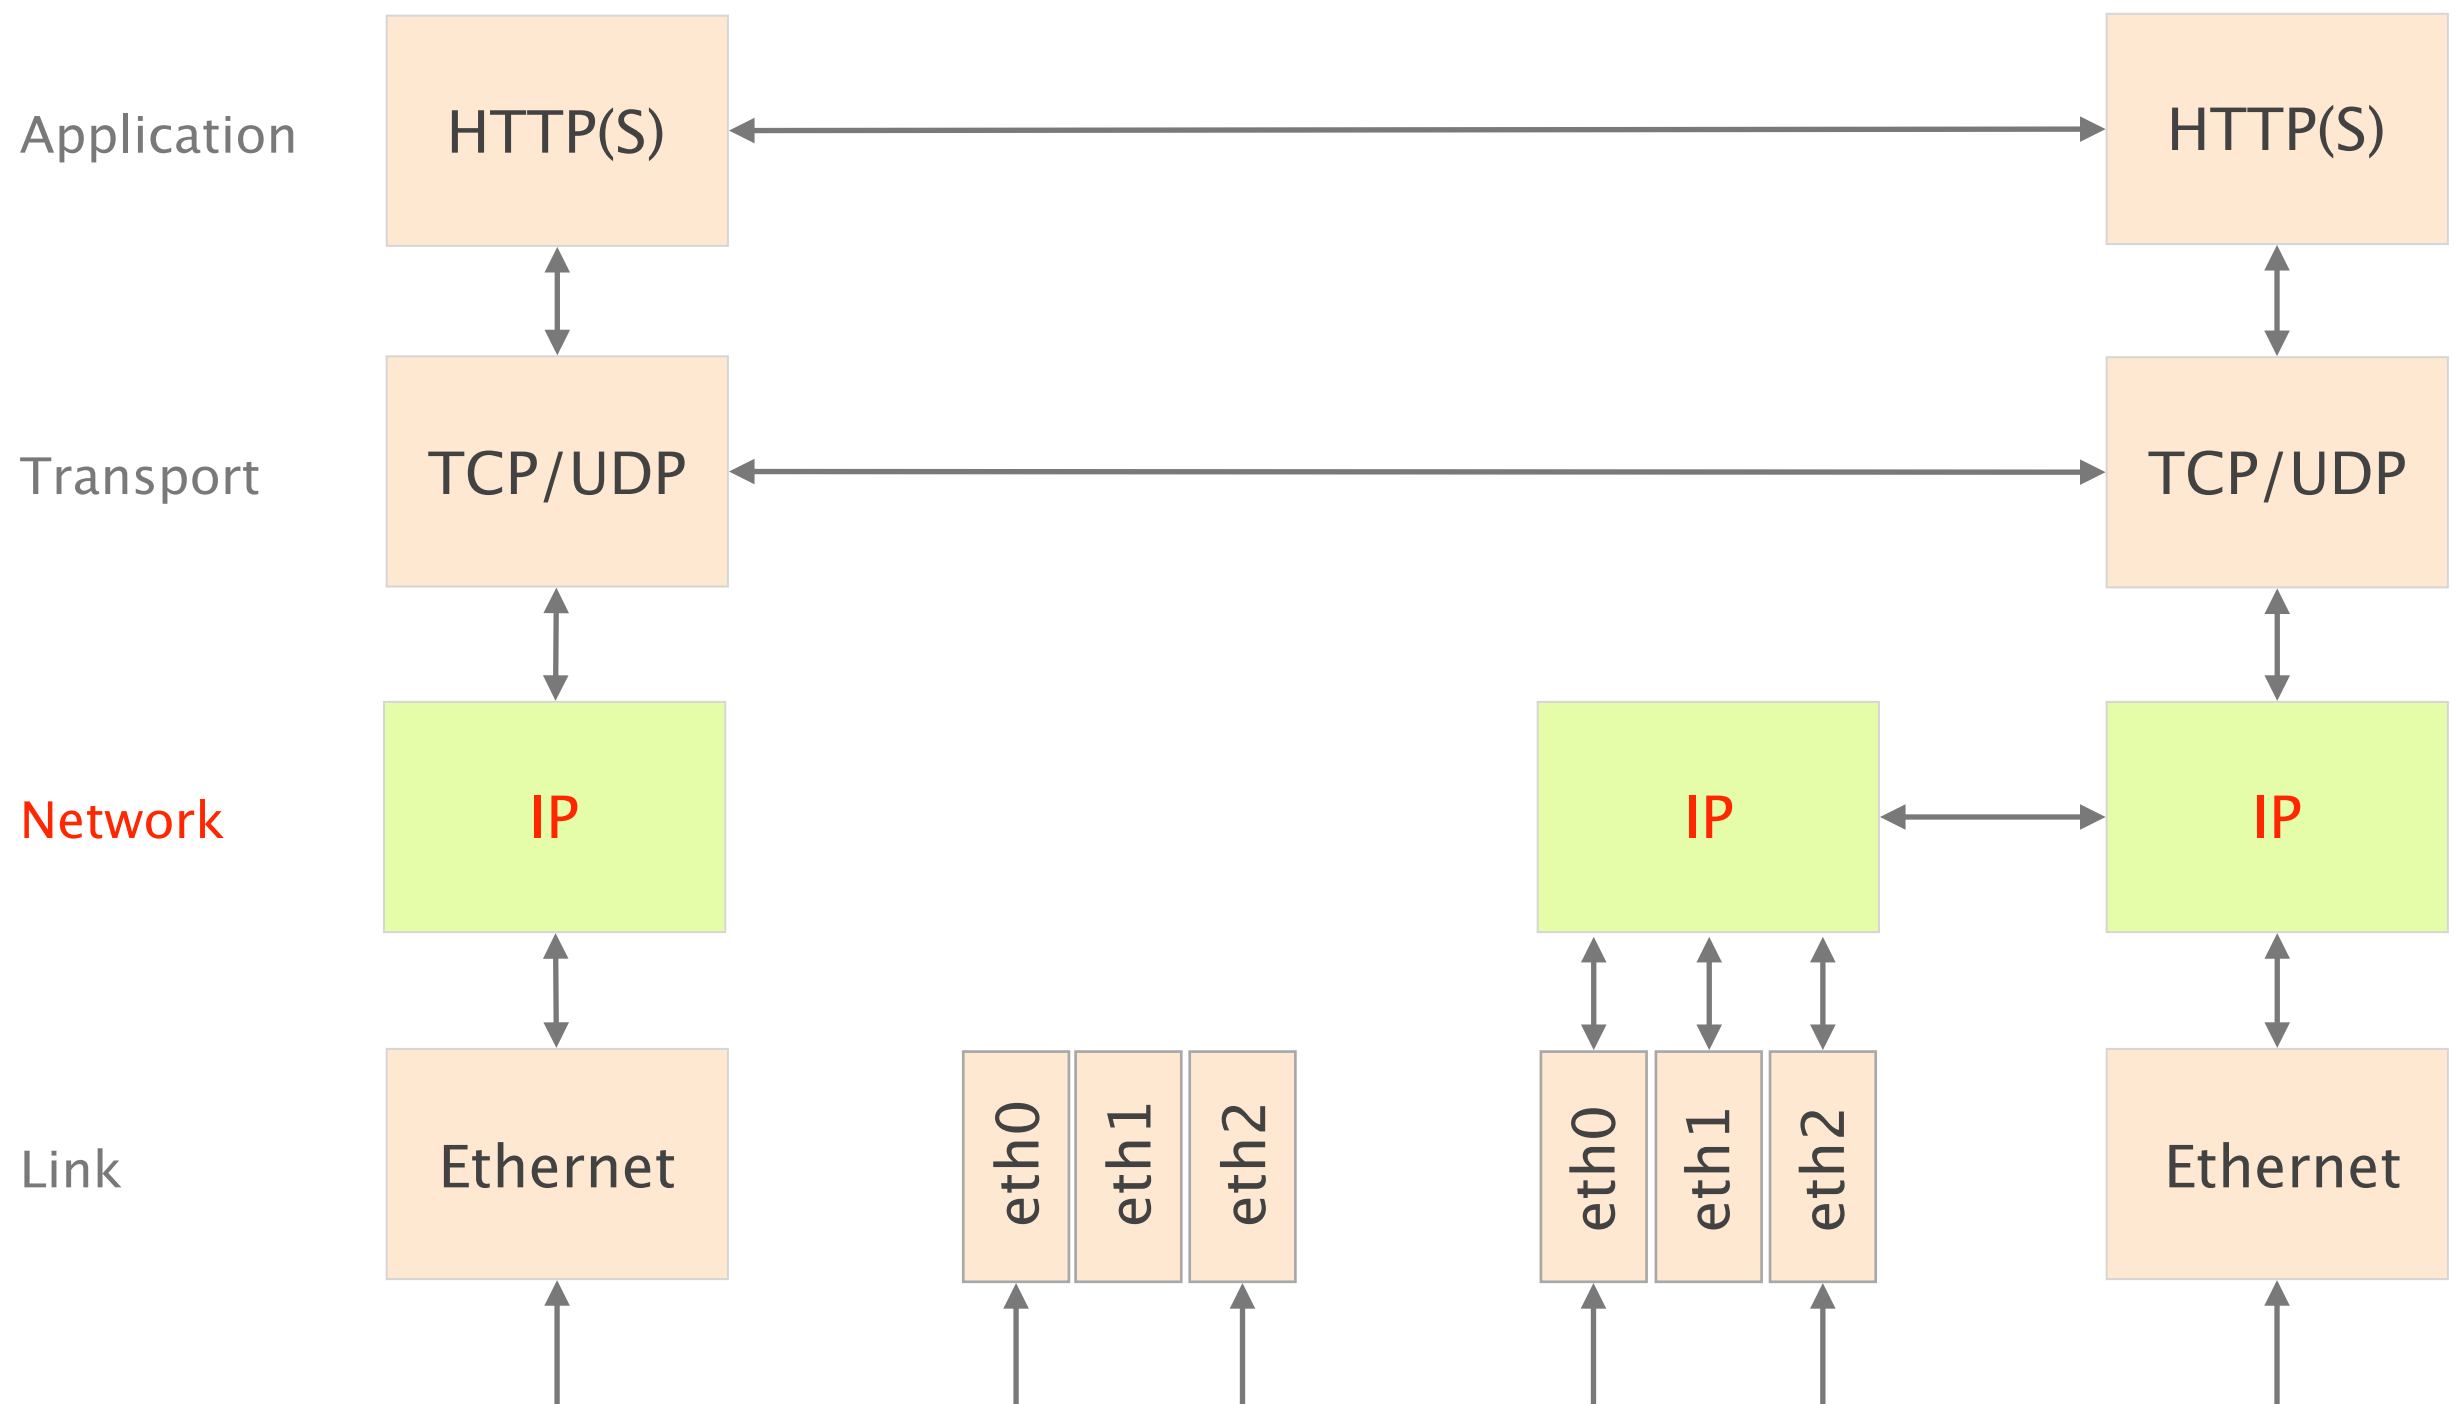

Link Layer

The diagram consists of two rectangular boxes. The left box is light orange and contains the text 'Link Layer'. The right box is light green and contains the text 'Network Layer'. Both boxes have a thin black border. The boxes are positioned horizontally next to each other.

Network Layer

The Beginning

Moving on to IP and the network layer

Internet Protocol and Forwarding

source: Boardwatch Magazine

- 1 **IP addresses**
use, structure, allocation
- 2 **IP forwarding**
longest prefix match rule
- 3 **IP header**
IPv4 and IPv6, wire format

Internet Protocol and Forwarding

1 IP addresses use, structure, allocation

IP forwarding
longest prefix match rule

IP header
IPv4 and IPv6, wire format

IPv4 addresses are unique 32-bits number
associated to a network interface (on a host, a router, ...)

IP addresses are usually written
using dotted-quad notation

Routers forwards IP packets
based on their destination IP address

If IP addresses were assigned arbitrarily,
routers would require **forwarding entries for all of them**

18 billion

estimated* # of Internet connected devices
in 2017

* Cisco Visual Networking Index 2017—2022

28.5 billion

estimated* # of Internet connected devices
in 2022

* Cisco Visual Networking Index 2017—2022

Two universal tricks you can apply to any computer sciences problem

When you need... more flexibility,
you add... a layer of indirection

When you need... more scalability,
you add... a hierarchical structure

When you need... more scalability,
you add... a hierarchical structure

IP addresses are hierarchically allocated,
similarly to the postal service

Address

Zip 8092

Street Gloristrasse

Building 35 (ETZ)

Location G 90
in building

Name Laurent Vanbever

Nobody in the Swiss mail system knows
where every single house or building is

principle

Routing tables are separated
at each level of the hierarchy

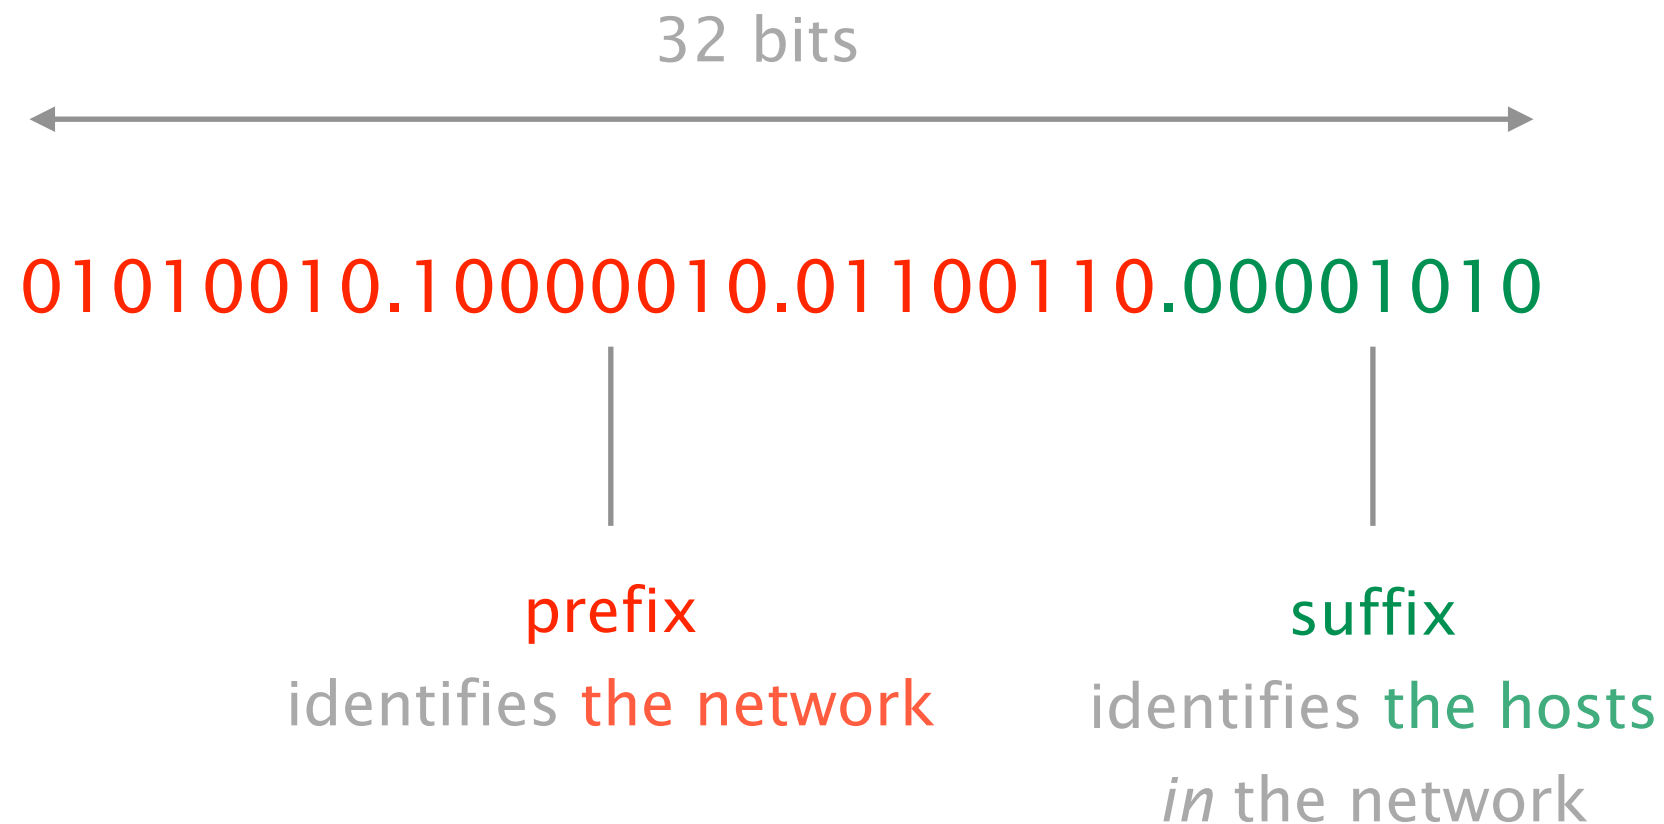

each one with a manageable scale

Forwarding in the Swiss mail

in 4 steps

- 1 Deliver the letter to the post office responsible for the zip code
- 2 Assign letter to the mail person covering the street
- 3 Drop letter into the mailbox attached to the building
- 4 Hand in the letter to the appropriate person

IP addressing is hierarchical, composed of a prefix (network address) and a suffix (host address)

Each prefix has a given length,
usually written using a “slash notation”

IP prefix 82.130.102.0 /24

 |

 prefix length (in bits)

Here, a /24 means that we have 8 bits left
to address hosts address, **enough for 256 hosts**

82.130.102.0 /24

prefix part

host part

IP address

01010010.10000010.01100110.

00000000

82.130.102.0

01010010.10000010.01100110.

00000001

82.130.102.1

01010010.10000010.01100110.

00000010

82.130.102.2

01010010.10000010.01100110.

11111110

82.130.102.254

01010010.10000010.01100110.

11111111

82.130.102.255

In practice, the first and last IP address of a prefix are not usable

prefix part

host part

IP address

01010010.10000010.01100110.

00000000

82.130.102.0

01010010.10000010.01100110.

11111111

82.130.102.255

The address with the host part being all 0s identifies the network itself

prefix part

host part

IP address

01010010.10000010.01100110.

00000000

82.130.102.0

The address with the host part being all 1s identifies the broadcast address

prefix part

host part

IP address

01010010.10000010.01100110.

11111111

82.130.102.255

A /24 has therefore only 254 addresses
that can be allocated to hosts

Prefixes are also sometimes specified
using an address and a mask

| | |
|---------|--------------------------------------|
| Address | 82.130.102.0 |
| | 01010010.10000010.01100110. 00000000 |
| | 11111111.11111111.11111111. 00000000 |
| Mask | 255.255.255.0 |

ANDing the address and the mask
gives you the prefix

Address 82.130.102.0

01010010.10000010.01100110. 00000000

11111111.11111111.11111111. 00000000

Mask 255.255.255.0

Given this IP prefix

82.130.0.0/17

Compute

of addressable hosts

the prefix mask

network address

1st host address

last host address

broadcast address

Routers forward packet to their destination
according to the network part, *not* the host part

Doing so enables to scale the forwarding tables

Hierarchical addressing enables to add new hosts without changing or adding forwarding rules

Originally, there were only 5 fixed allocation sizes,
(or classes)—known as classful networking

| | leading bits | prefix length | # hosts | start address | end address |
|----------------------|-----------------|------------------|------------|------------------|-----------------|
| class A | 0 | 8 | 2^{24} | 0.0.0.0 | 127.255.255.255 |
| class B | 10 | 16 | 2^{16} | 128.0.0.0 | 191.255.255.255 |
| class C | 110 | 24 | 2^8 | 192.0.0.0 | 223.255.255.255 |
| class D multicast | 1110 | | | 224.0.0.0 | 239.255.255.255 |
| class E reserved | 1111 | | | 240.0.0.0 | 255.255.255.255 |

Classful networking was quite wasteful leading to IP address exhaustion

problem

Class C was too small, so everybody requested class B
which where: *i)* too big and *ii)* too few (wasted space)

solution

Classless Inter-Domain Routing (CIDR)
introduced in 1993

CIDR enabled flexible division between network and hosts addresses

CIDR must specify both the address and the mask
classful was communicating this in the first address bits

Masks are carried by the routing algorithms
it is *not* implicitly carried in the address

Say that an organization needs 500 addresses...

| with... | it gets a... | leading to a waste of... |
|----------|--------------------|--------------------------|
| classful | class B (/16) | 99% |
| CIDR | /23 (=2 class C's) | 2% |

With CIDR, the max. waste is bounded to 50% (why?)

Today, addresses are allocated in contiguous chunks

As of now,
the Internet has around 710,000 IPv4 prefixes

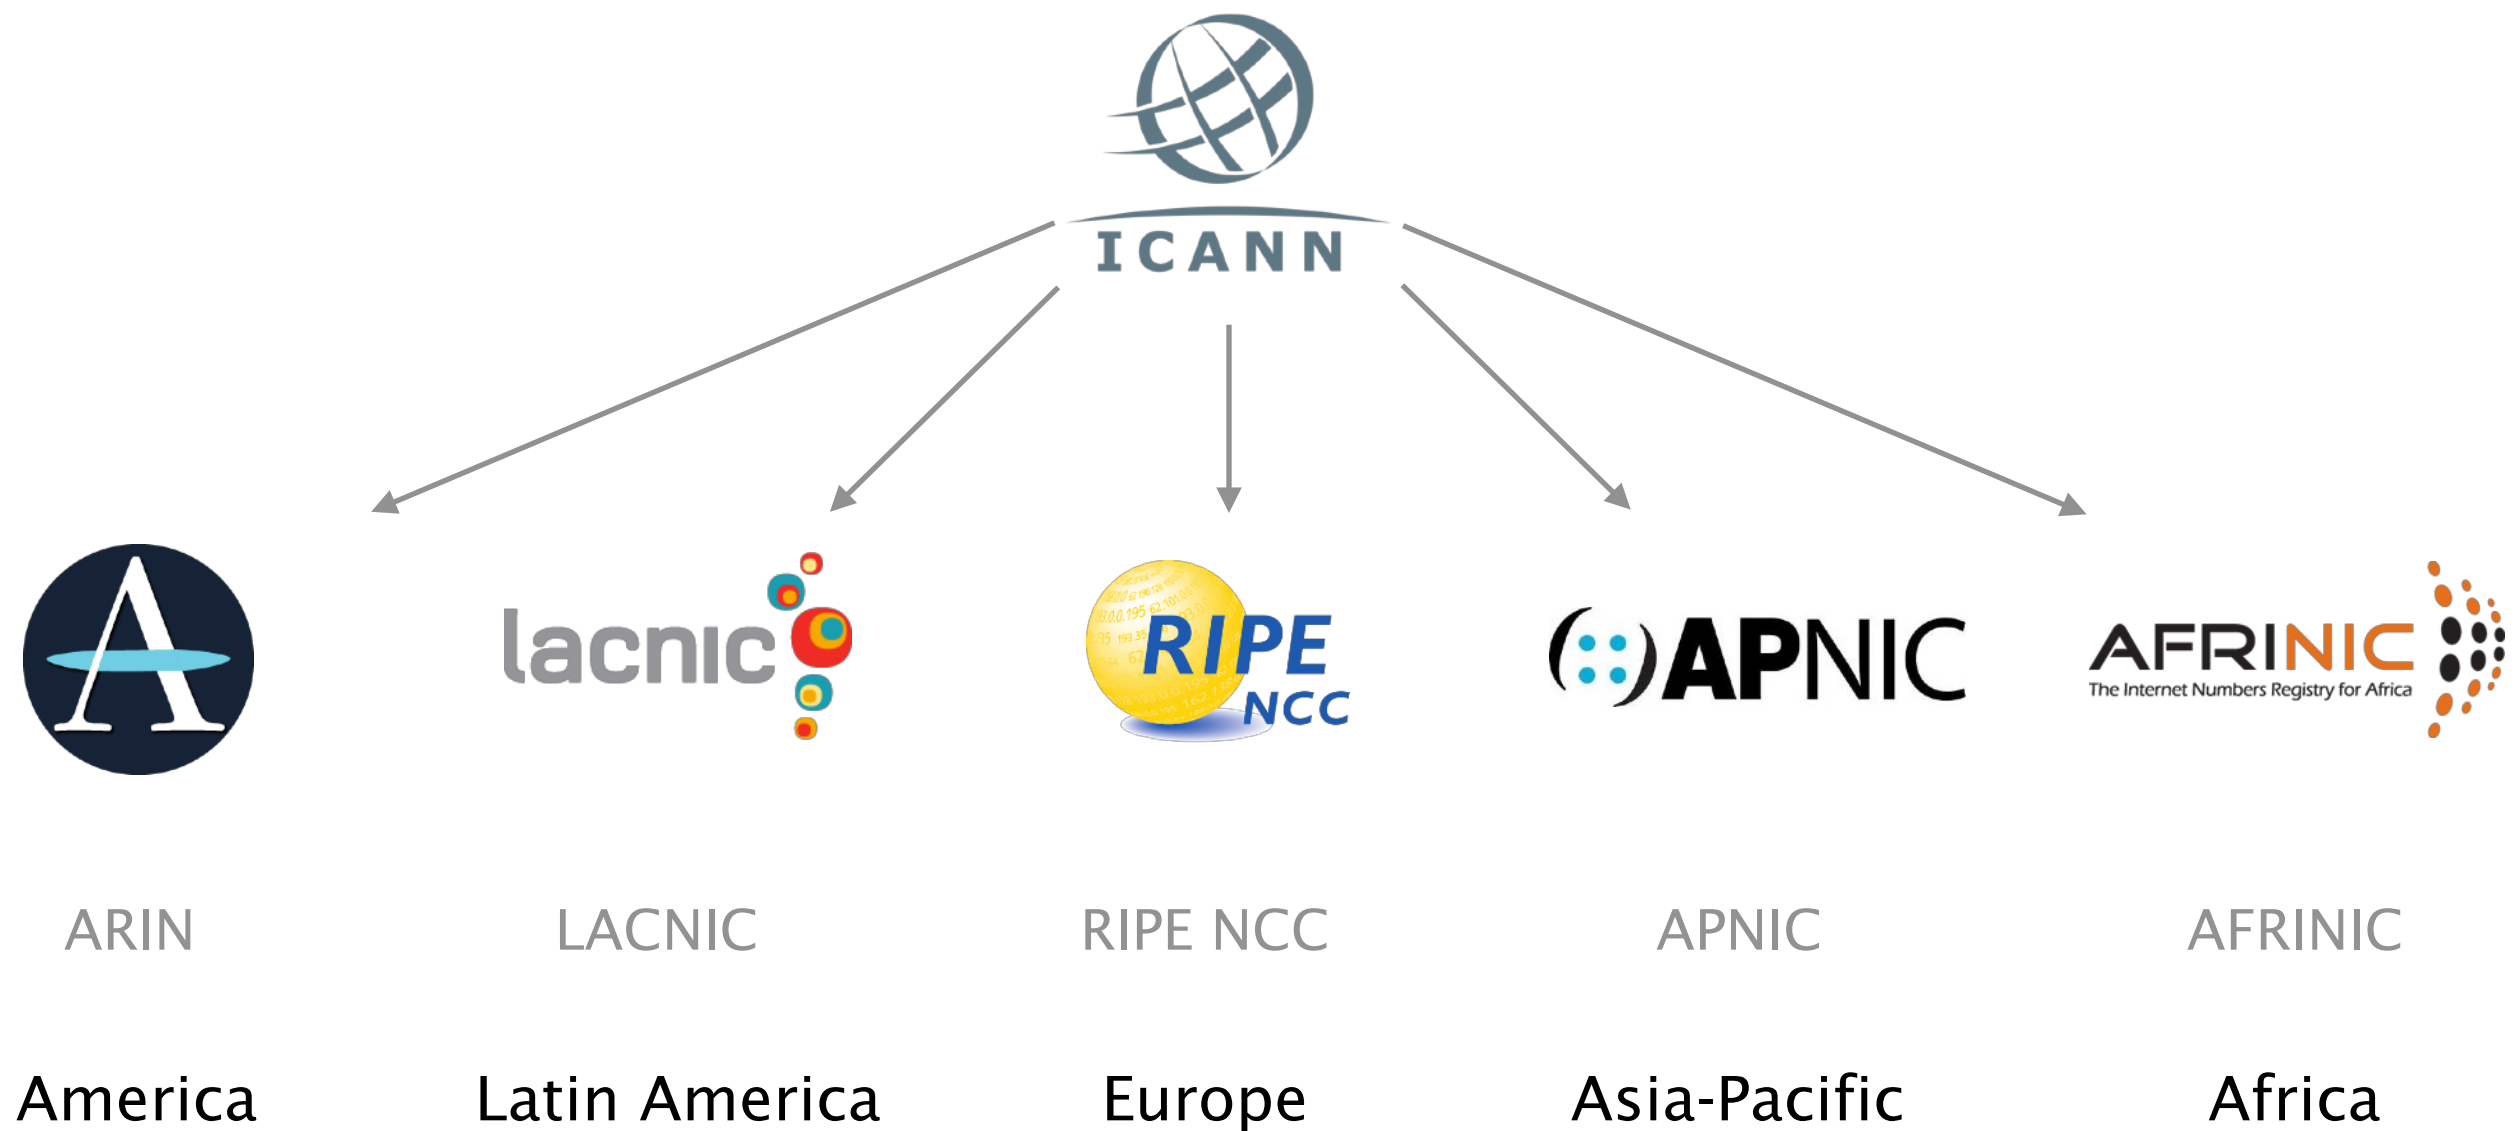

source <http://www.cidr-report.org/>

The allocation process of IP address is also hierarchical

The root is held by Internet Corporation for
Assigned Names and Numbers, aka ICANN

ICANN allocates large prefixes blocks to Regional Internet Registries (RIRs)

RIRs allocates parts of these prefixes blocks to Internet Service Providers (ISPs) and large institutions

ISPs and large institutions may, in turn,
allocate even smaller prefixes to their own customers

ICANN gives RIPE

82.0.0.0/8

Prefix

01010010

RIPE gives ETHZ

82.130.64.0/18

Prefix

010100101000001001

ETHZ gives ITET/TIK

82.130.102.0/23

Prefix

01010010100000100110011

DITET

ITET gives me

82.130.102.254

Address

0101001010000010011001101111110

IP prefixes @

1 82.130.64.0/18

2 129.132.0.0/16

3 148.187.192.0/19

4 195.176.96.0/19

5 192.33.87.0/24

6 192.33.88.0/21

7 192.33.96.0/21

8 192.33.104.0/22

9 192.33.108.0/23

10 192.33.110.0/24

Internet Protocol and Forwarding

IP addresses

use, structure, allocation

2

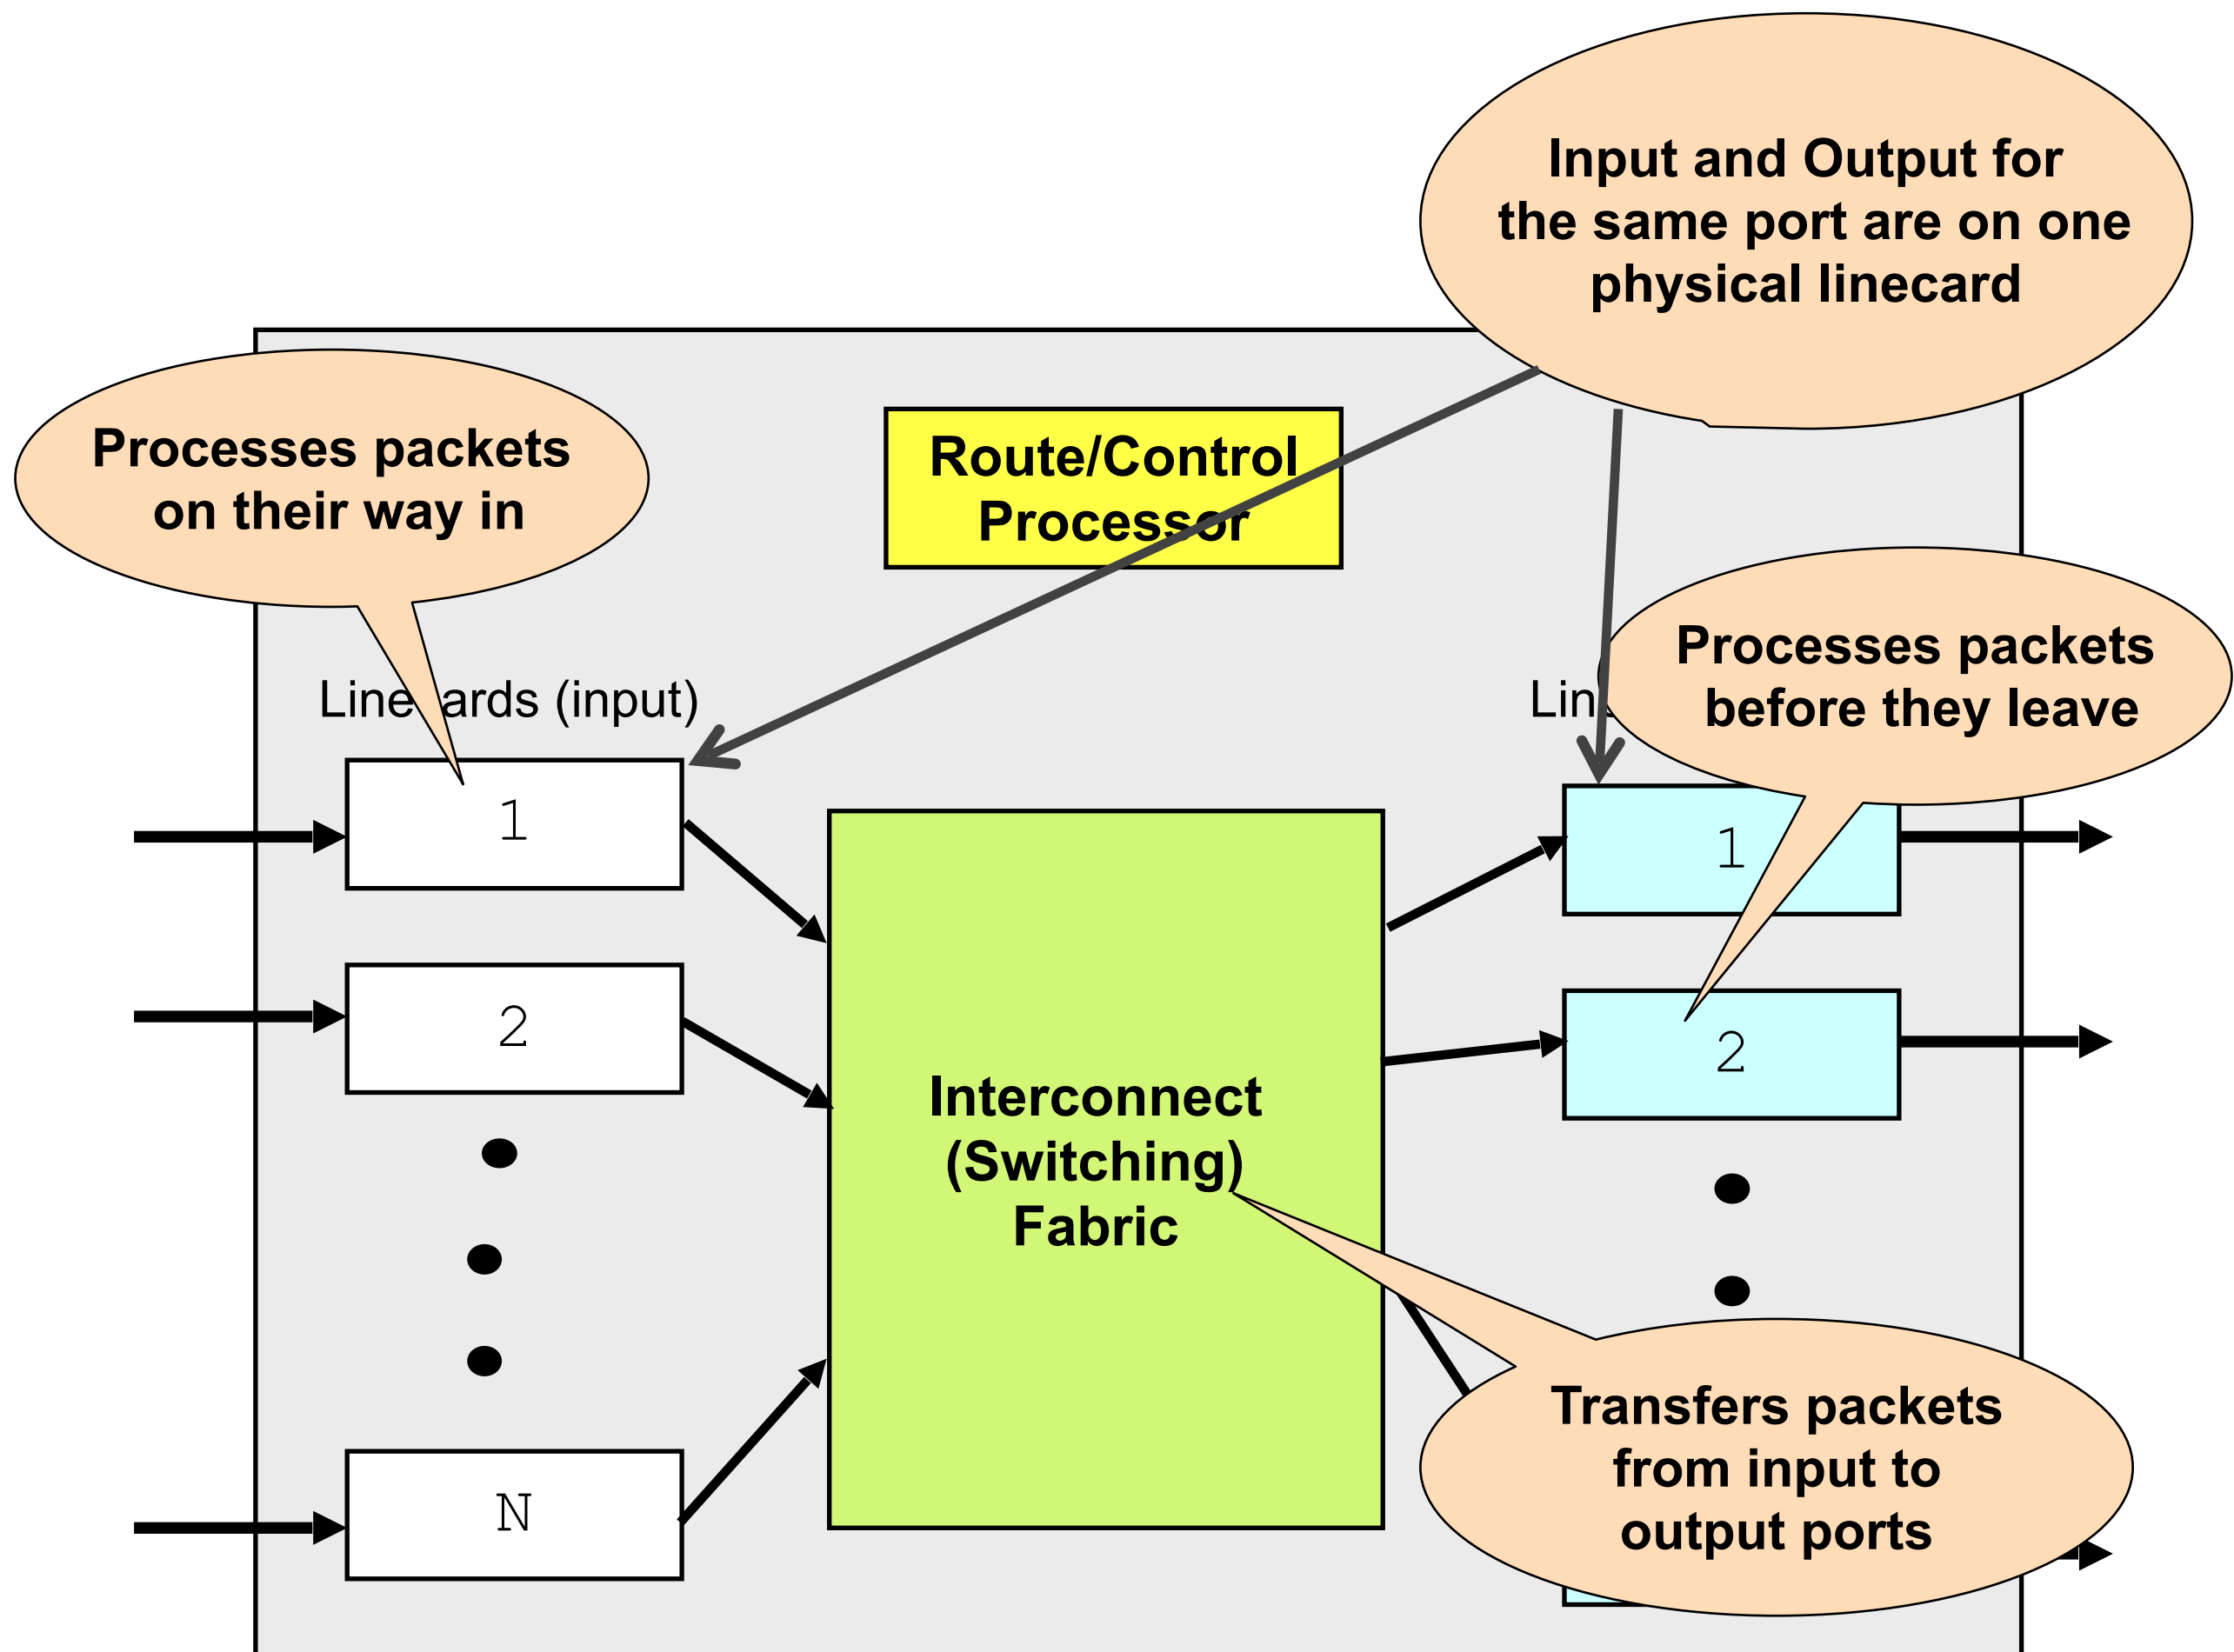

IP forwarding

longest prefix match rule

IP header

IPv4 and IPv6, wire format

What's inside an IP router?

Routers maintain forwarding entries
for each Internet prefix

Provider 2's Forwarding table

| IP prefix | Output |
|----------------|--------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

Let's say a packet for 129.0.1.1
arrives at Provider 2

Provider 2's Forwarding table

| IP prefix | Output |
|----------------|--------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

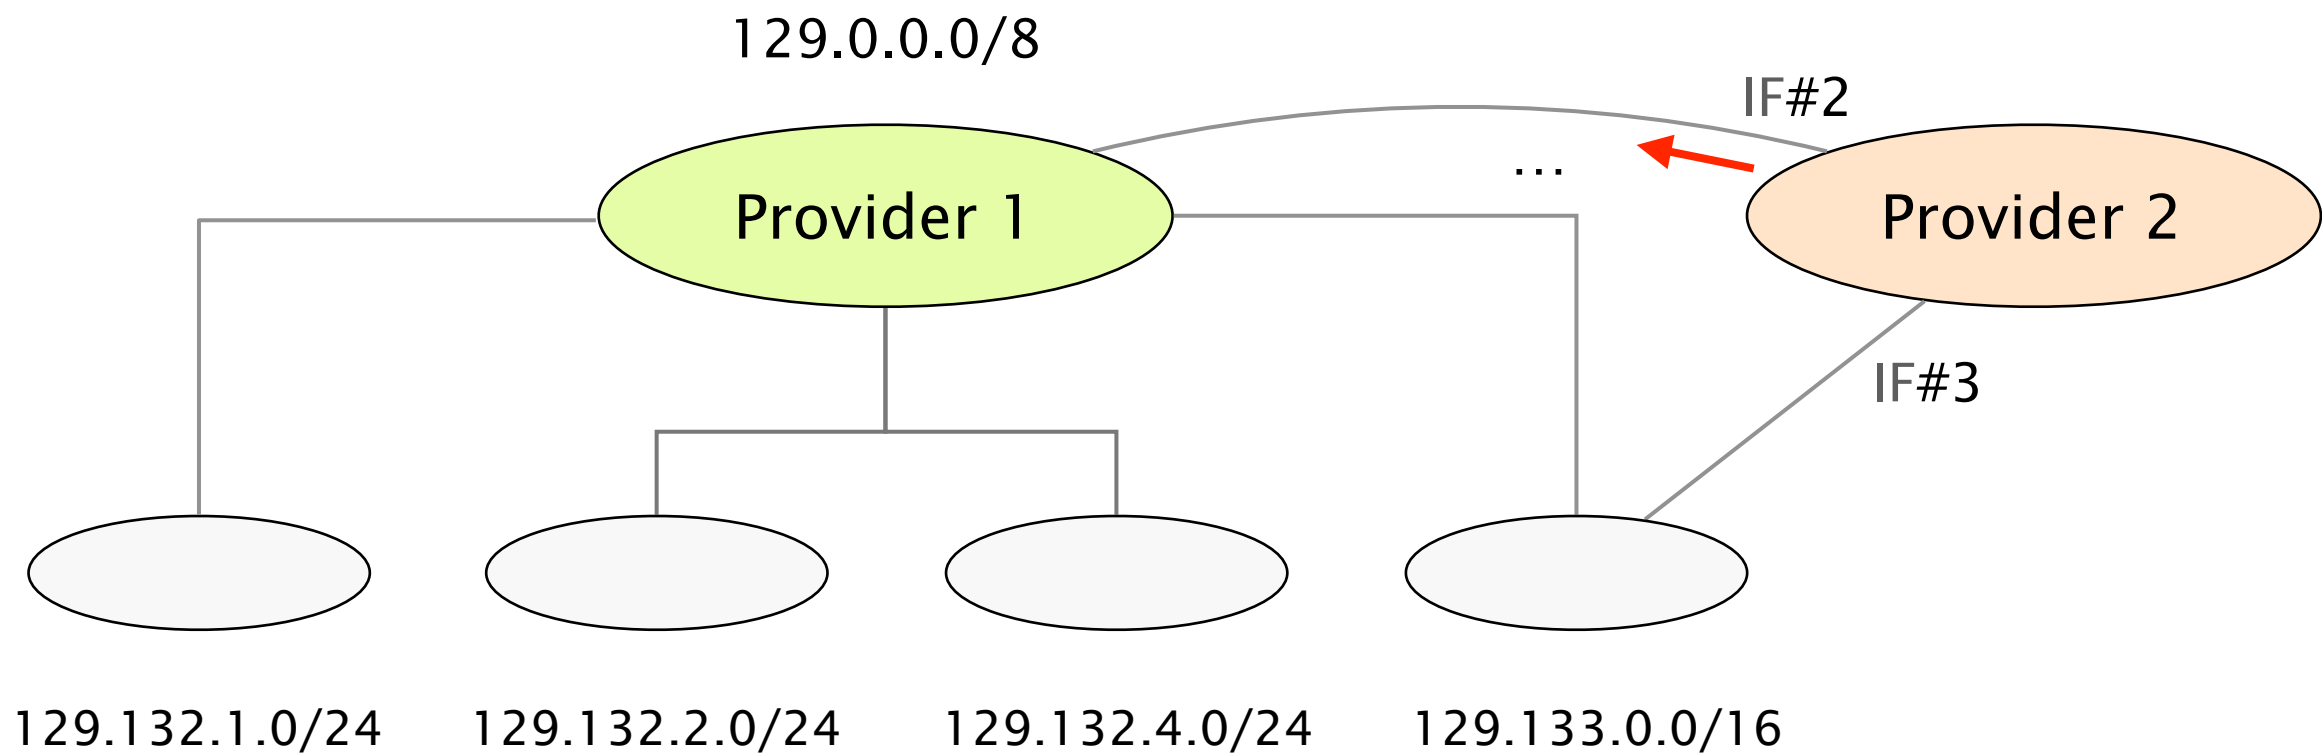

When a router receives an IP packet, it performs an IP lookup to find the matching prefix

Let's say a packet for **129.0.1.1**
arrives at Provider 2

> **Provider 2 forwards it to IF#2**

Provider 2's Forwarding table

| IP prefix | Output |
|--------------------|-------------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

CIDR makes forwarding harder though,
as one packet can match many IP prefixes

Let's say a packet for 129.133.0.1
arrives at Provider 2

Provider 2's Forwarding table

| IP prefix | Output |
|----------------|--------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

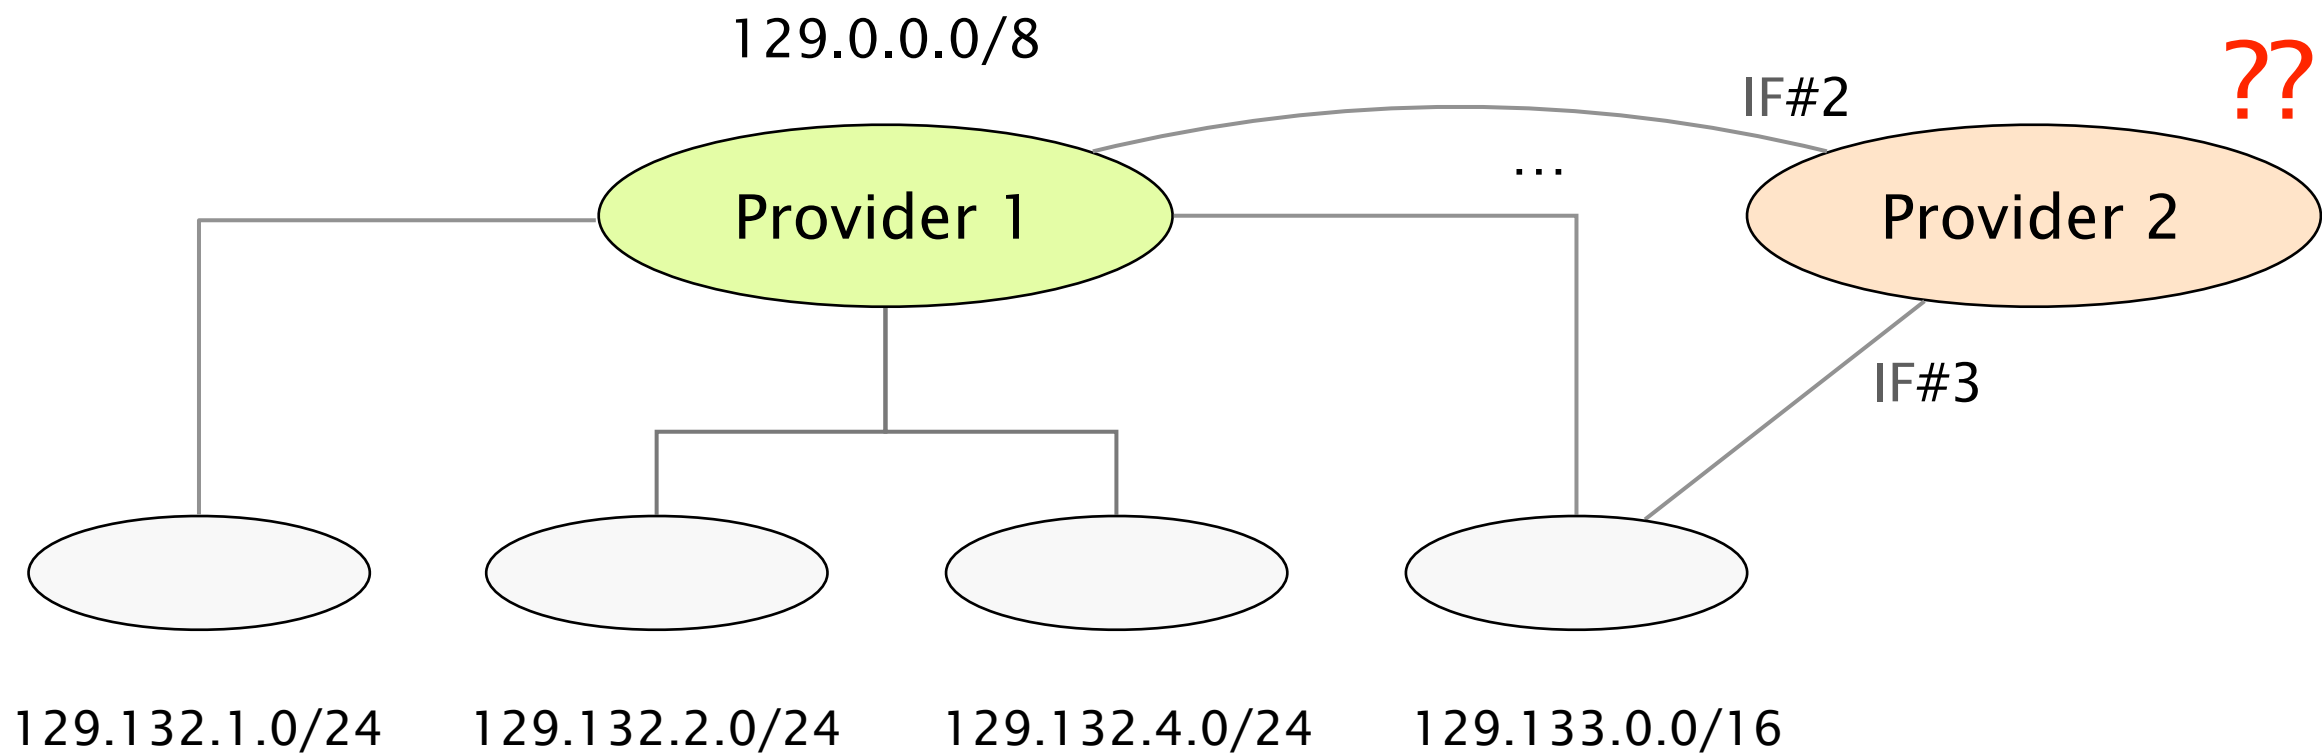

Let's say a packet for **129.133.0.1** arrives at Provider 2

We have two matches!

Provider 2's Forwarding table

| IP prefix | Output |
|-----------------------|-------------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

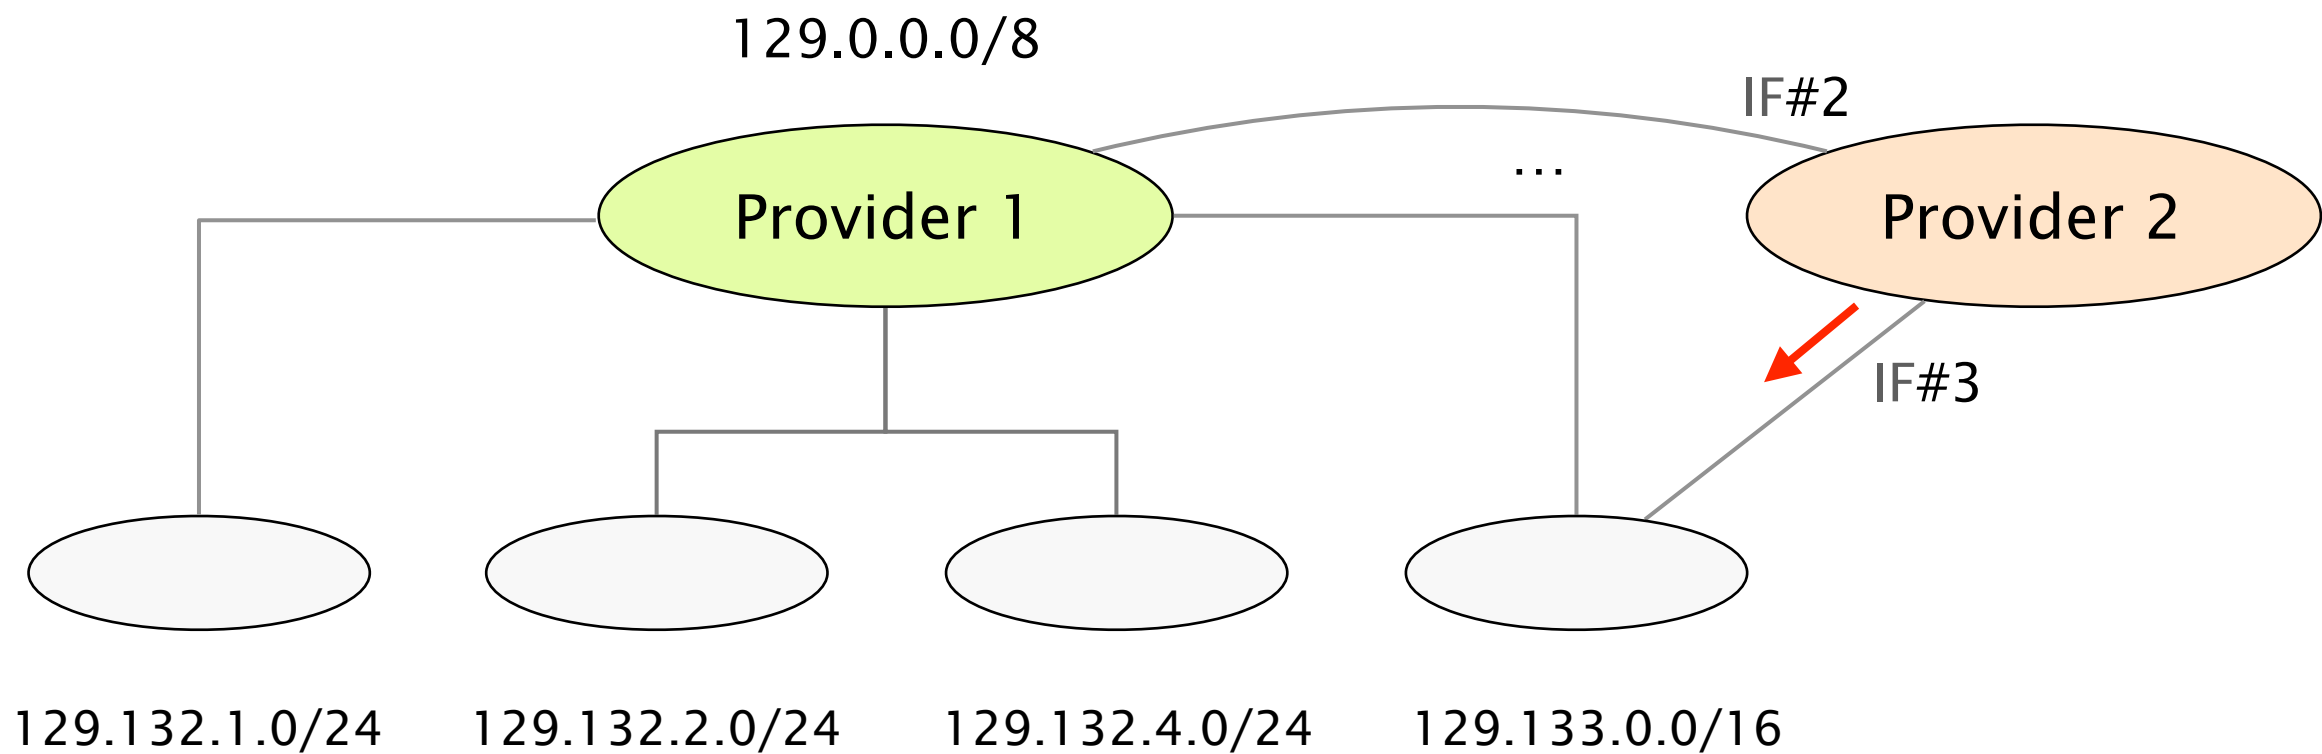

To resolve ambiguity, forwarding is done along the *most specific* prefix (*i.e.*, the longer one)

Let's say a packet for **129.133.0.1** arrives at Provider 2

> **Provider 2 forwards it to IF#3**

Provider 2's Forwarding table

| IP prefix | Output |
|-----------------------|-------------|
| 129.0.0.0/8 | IF#2 |
| 129.132.1.0/24 | IF#2 |
| 129.132.2.0/24 | IF#2 |
| 129.133.0.0/16 | IF#3 |

Could we do something better than
maintaining one entry per prefix? *Yep!*

A child prefix can be filtered from the table whenever it shares the same output interface as its parent

Internet Protocol and Forwarding

IP addresses

use, structure, allocation

IP forwarding

longest prefix match rule

3

IP header

IPv4 and IPv6, wire format

Here is what an IPv4 packet look like
on a wire

The version number tells us what other fields to expect, typically it is set to “4” for IPv4, or “6” for IPv6

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The header length denotes the number of 32-bits word in the header, typically set to 5 (20 bytes header)

| | | | | |
|------------------------|------------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The ToS allows different packets to be treated differently,
e.g., low delay for voice, high bandwidth for video

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The total length denotes the # of bytes in the entire packet, with a maximum of 65 535 bytes

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The next three fields are used when packets
get **fragmented**

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | | Protocol | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

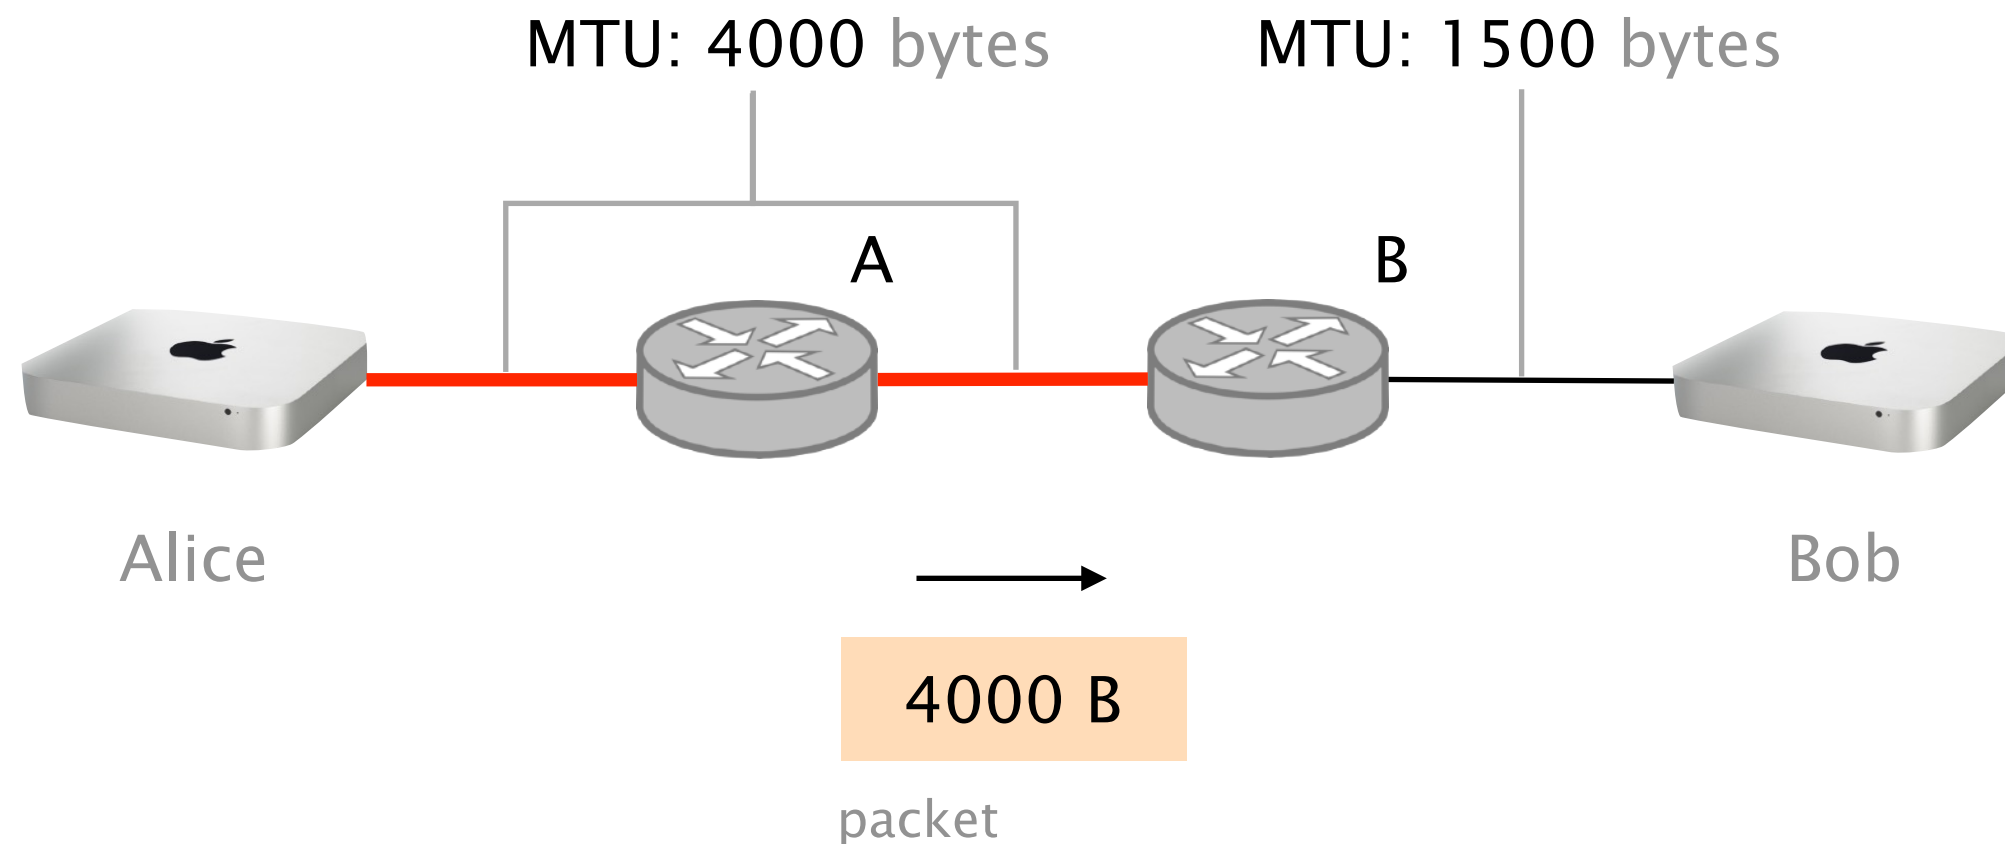

Every link in the Internet has a Maximum Transmission Unit (MTU)

MTU is the max. # of bytes a link can carry as one unit
e.g., 1500 bytes for normal Ethernet

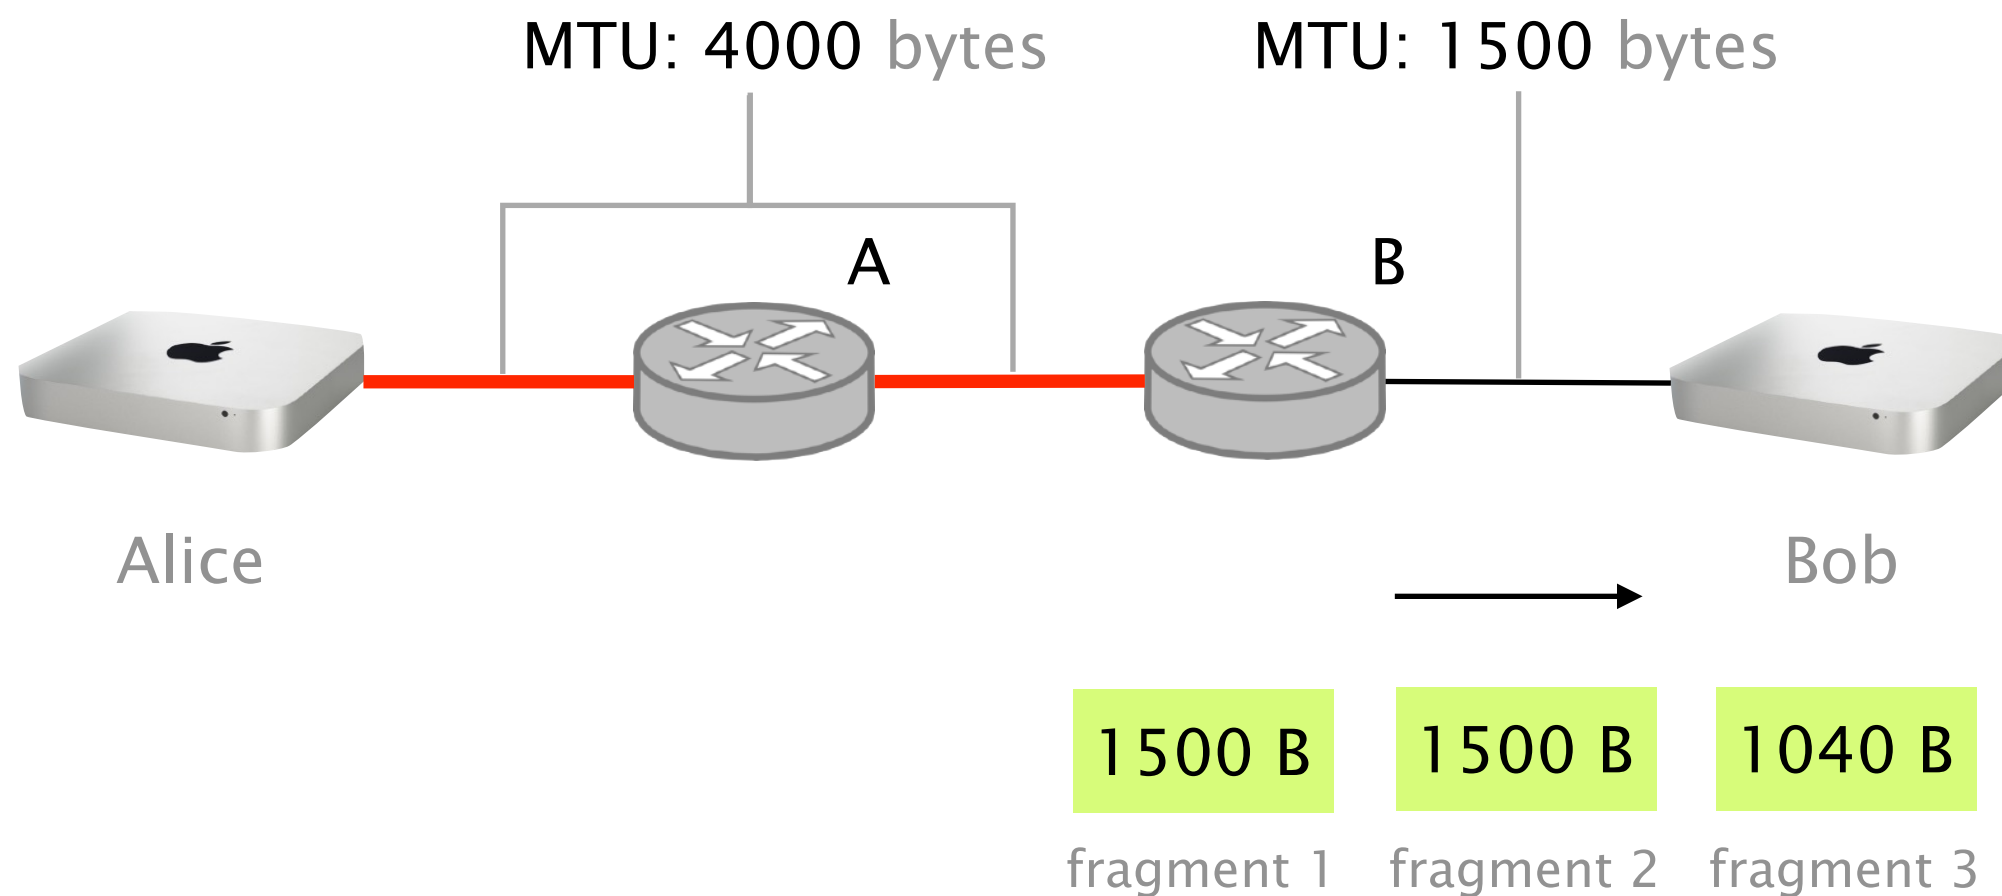

A router can fragment a packet if the outgoing link MTU
is smaller than the total packet size

Fragmented packets are recomposed at the destination
why not in the network?

Assume Alice is sending 4000B packets to Bob,
who is connected to a 1500B MTU link

Because the packet is larger than the MTU,
router B will split the packet into fragments

IP header

4000

20

3980

20

1480

20

1480

1020

1500

1500

1040

The Identification header uniquely identify the fragments of a particular packet

| | | | | |
|------------------------|------------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | | Protocol | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The fragment offset is used to put back the fragments in the right order in case of reordering

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The flags is used to tell whether there are more fragments coming or not

| | | | | |
|------------------------|------------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | | Protocol | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The TTL is used to identify packets trapped in a loop, and eventually discard them

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | | Protocol | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

TTL is decremented by 1 at each router,
the packet is discarded if it reaches 0

default TTL values

| | |
|------------------|-----|
| *nix (Linux/Mac) | 64 |
| Windows | 128 |

(used for OS fingerprinting)

The protocol field identifies the higher level protocol carried in the packet, “6” for TCP, “17” for UDP

| | | | | |
|------------------------|------------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The checksum is the sum of all the 16 bits words in the header (does not protect the payload)

| | | | | |
|------------------------|---------------|-----------------|--------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | Header checksum | | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

The source and destination IP uniquely identifies the source and destination host

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |
| Payload | | | | |

Options were initially put to provide additional flexibility.
For security reasons, there are often deactivated.

| | | | | |
|------------------------|---------------|-----------------|-----------------|-----------------------|
| version | header length | Type of Service | Total Length | |
| Identification | | | Flags 3 | Fragment offset 13 |
| Time To Live | Protocol | | Header checksum | |
| Source IP address | | | | |
| Destination IP address | | | | |
| Options (if any) | | | | |

see <http://www.networksorcery.com/enp/protocol/ip.htm#Options> for a full list

While there are no new IPv4 available,
IPv4 still accounts for most of the Internet traffic (for now)

IPv4

With respect to IPv4,
IPv6 is simpler

IPv6 was motivated by address exhaustion

IPv6 addresses are 128 bits long, that's plenty!

IPv6 got rid of anything that wasn't necessary
spring cleaning

Result is an elegant, if unambitious, protocol

With respect to IPv4, IPv6 is simpler

IPv6

removed

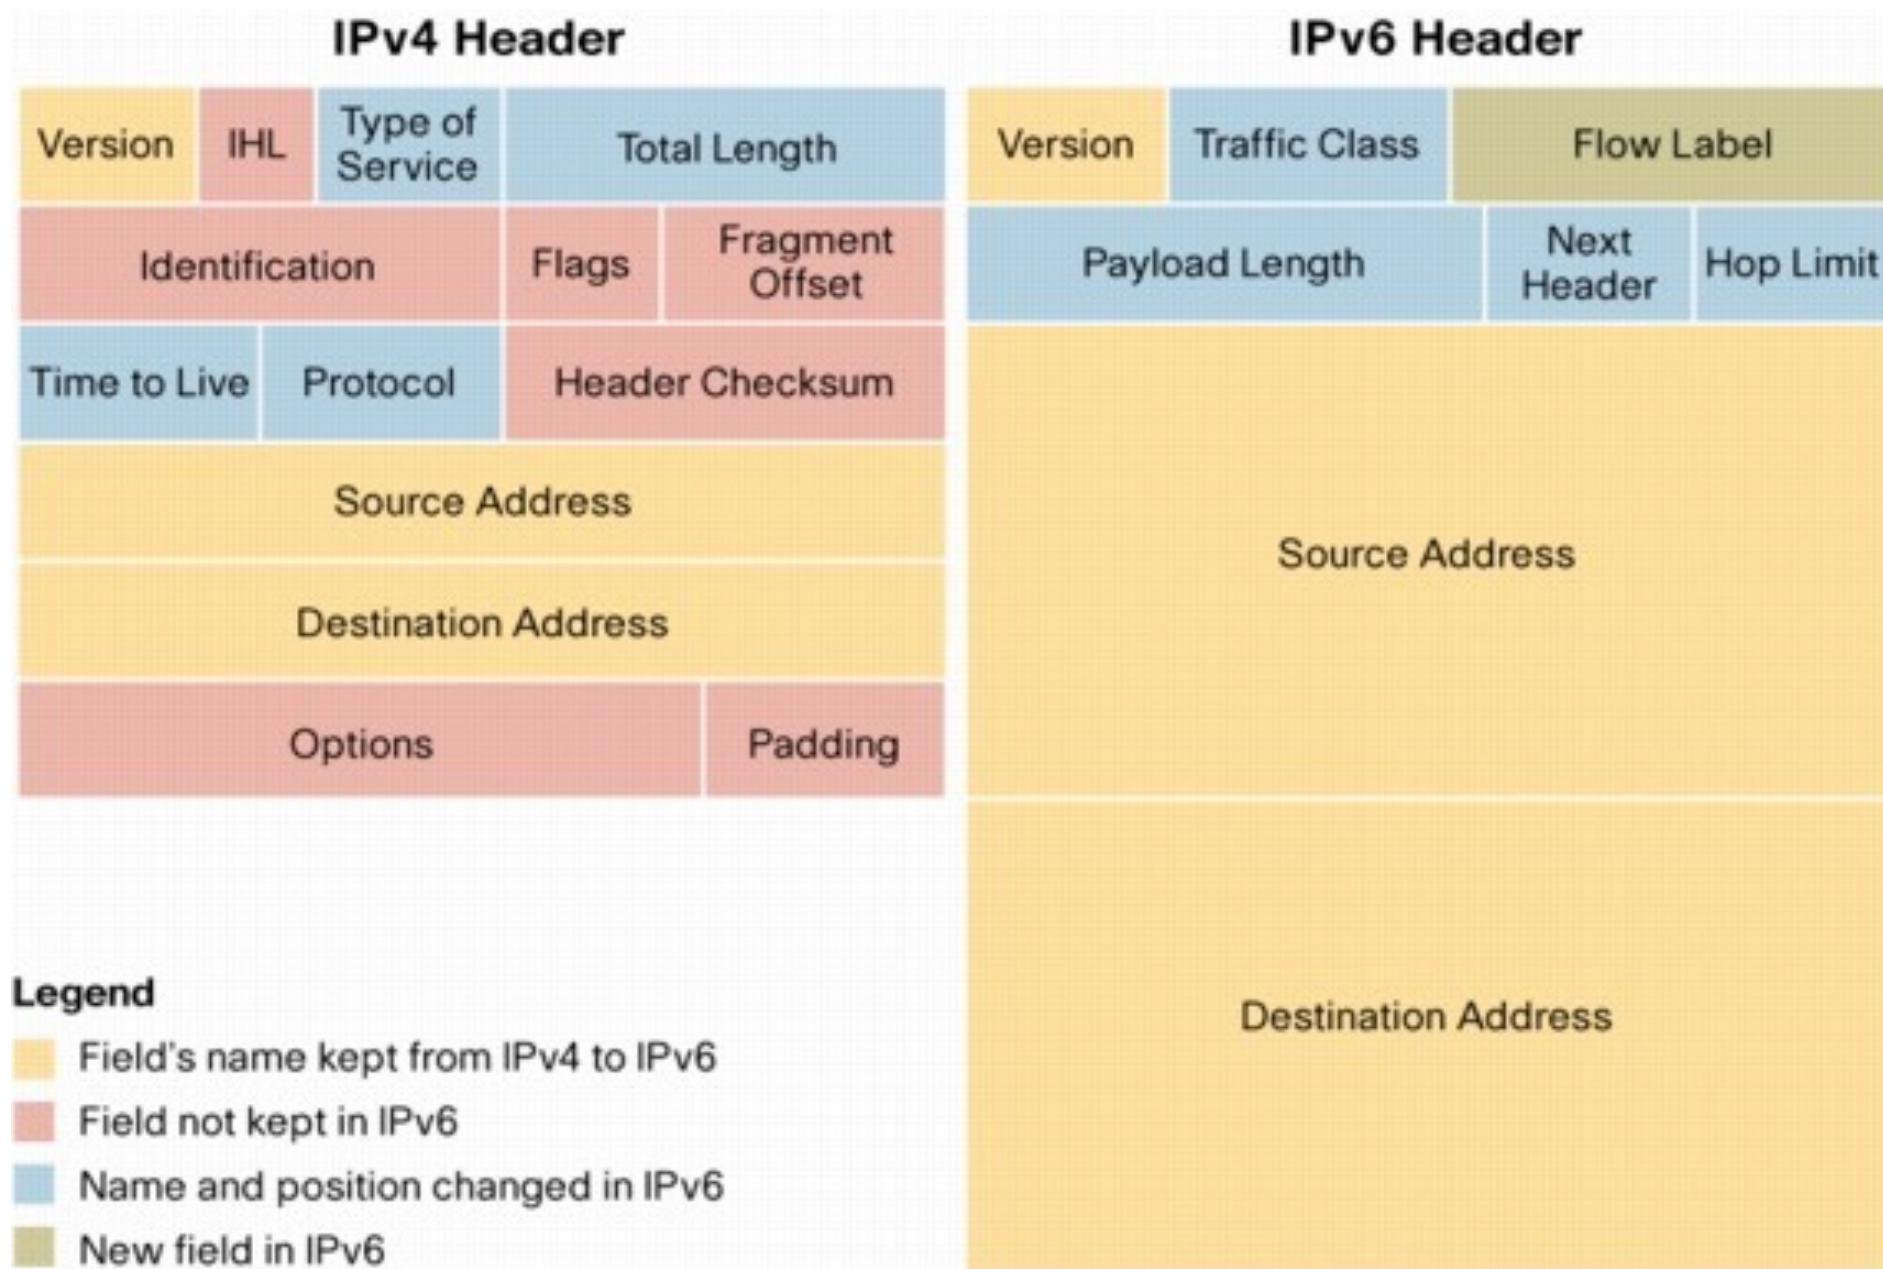

reason

IPv4 vs IPv6

IPv6 enables to insert arbitrary options in the packet
see RFC 2460

The problem with IPv4 options is that all of them must be processed by each router, which is slow

In IPv6, only one type of optional header must be processed by each router

Internet Protocol and Forwarding

IP addresses

use, structure, allocation

IP forwarding

longest prefix match rule

IP header

IPv4 and IPv6, wire format
